INFORMATION TECHNOLOGY SOCIAL SYSTEMS: THE MYCITE PROJECT, WHAT IS AT RISK, MITIGATING HARM, VALUE PROPOSITION, & WHAT IS BEING DONE

AUTHORED BY: DYLAN MONTGOMERY

ABSTRACT

The Mycite Project is a mission-driven effort to support public awareness of systemic information problems and to develop the Mycite Framework Technology as a solution. This report outlines the need to establish a new foundation for the information technology industries approach. One that recognizes the impossibility of information ownership, addresses the threats posed by continued adherence to outdated models, and proposes a decentralized, standards-based system for the ethical and resilient use of information.

1. INTRODUCTION

In the modern world, our lives are shaped by systems built around a dangerous misconception: that information can be owned. This fallacy underpins today's digital economies, surveillance regimes, and power structures, and those structures are rapidly becoming incompatible with accelerating technological progress. Quantum computing, artificial intelligence, and ubiquitous connectivity are not merely adding new layers; they are eroding the foundations on which the old layers were built.

Societies therefore appear to face a binary choice: cling to failing institutions until they fracture, or double-down on control through ever-tighter surveillance and digital authoritarianism. A third path exists. It demands new assumptions, new governance, and a new digital infrastructure. One that treats information not as a commodity to be contained but as a force of nature to be stewarded. The Mycite Project is a response to this moment. It argues that social systems must shift from containment-based models of information control to contribution-based models of interaction. This shift is both moral and practical: just as energy cannot be owned, only harnessed, information must be allowed to flow, recombine, and self-discover. The question is not whether this transformation will come, but whether we will meet it with foresight or be overtaken by crisis.

1.1 TECHNOLOGY; A POWER MULTIPLIER

Throughout history, each breakthrough has acted like a support post for a young tree: it props growth at first, then gradually constricts the trunk until it must be cut away. Shared fire circles, agriculture, coined money, written language, steam engines, broadcast media, and finally the internet. All multiplied humanity's capability and entrenched the hierarchies that first deployed them. Once entrenched, every post ossifies: it preserves yesterday's winners while throttling tomorrow's growth.

Today's posts, cloud monopolies, DRM fortresses, and data-ownership statutes, now choke the very networks they once enabled. Excessive power again concentrates in a narrow stratum, defended as "natural order." But the historical rhythm is clear: constriction always precedes a redistribution of capability. Whether by upheaval or redesign, the post must give way.

We stand at that moment. Resisting decentralisation may buy time, but change, like unwelcome thought, resurfaces. The Mycite Project seeks to guide this inevitable shift toward stewardship and shared agency rather than chaos or coercion. We return to the power-cycle theme in §3.4; for now, we turn to the physics of information itself, the principles that any durable system must respect.

2. BACKGROUND

The study of Surrealmatics [*the philosophical and technical understanding of information as a natural force*] offers a critical lens for interpreting the present. Information exhibits characteristics analogous to physical forces: entropy, momentum, semantic density, and recursive structure. These traits reveal why the traditional model of ownership is not just impractical, but incompatible with the behavior of information itself.

Information, like energy, flows and disperses. Its value is not static, but created through intentional arrangement. As AI systems show, "creation" is merely the recombination of known elements into new arrangements. In a finite digital universe, such as all possible strings of a given character set, novelty is not invention, but discovery. As systems like language models traverse these possibility spaces, they blur the lines between author and algorithm, creator and tool.

At the same time, information is becoming denser and more accessible. Each discovery adds to a collective field of knowledge, accelerating our ability to build on prior work. Like a fractal, new truths emerge from recursive refinement, whether through deep, focused analysis or broad, high-level synthesis. This scaling behavior collapses traditional hierarchies of expertise and ownership, placing greater value on contribution, intentionality, and perspective.

Understanding these dynamics is essential. As with the physical world, ignoring the natural properties of a system does not prevent its consequences, it only increases their severity. The remainder of this report will examine the systems currently built on false premises of information ownership, the dangers they now pose, and the third-way alternative enabled by the Mycite Framework and its application in local, decentralized systems like agriculture.

2.1 CONSERVATION

The boundary between invention and discovery has eroded. This erosion is not a side effect of artificial intelligence but rather a

revelation made clear. It compels us to reconsider what it means to create when all possible arrangements of information already exist in a definable space. A thousand-character page, for instance, composed from a set of 29 characters (letters, space, punctuation), has a finite number of permutations. Though vast, that space is not infinite. It is mappable. In this context, AI does not invent. It navigates.

When we understand content as instances drawn from a larger field of possibilities, originality becomes a matter of intention and selection rather than exclusive creation. The act of choosing, interpreting, and arranging from a field of known components is what we value. Not the false notion that such arrangements can be owned.

The implications extend beyond AI and into all domains where creativity is celebrated and monetized. As machines outperform humans in navigating and rearranging data, our economy must shift from rewarding novelty of output to rewarding novelty of perspective. The artist, the thinker, the builder; they contribute not because their elements are new, but because their arrangement says something real.

2.2 ENTROPY

Entropy is the foundational principle that explains why information cannot be contained. It is a natural law of information that governs digital systems. Like energy in traditional physics tends to move from a confined system, information tends toward proliferation.

Today, digital infrastructure relies on encryption to enforce boundaries. Simply put, it allows points of contact to identify themselves across public lines of communication to establish a connection that is highly obfuscated. In essence, mathematical protocols are relied on to assume that a party is who they say they are and they are the only ones to be able to read information sent. These protocols work not by stopping information from spreading, but by obscuring it in such a way that only the right recipient can decipher it. Yet this fragile control mechanism faces extinction in the era of quantum computing. Despite the proposition of possible encryption methods that could solve shortcomings, in short, quantum computers will be capable of breaking the very foundations of our current encryption model.

Enormous amounts of encrypted data are currently being amassed and stored, driven by the anticipation of future decryption techniques. Notable progress in sensory interfacing has occurred, with research showing the ability to determine a person's focus of attention through brain stimulation patterns, eliminating the need for complex brain analysis. Piracy laws have become increasingly difficult to enforce, with it now understood that any information sent to a personal device can be intercepted. This has led major tech companies to restrict devices and claim ownership of operating software, effectively criminalizing the reverse engineering of device electronics. This centralization trend aims to support an economic system that values innovation and effort, operating under the assumption that there is no other way. However, entropy is unavoidable and building resilient systems requires working with it, which means transitioning from containing information to coordinating it.

Instead of locking data away, we must design systems that embrace openness, auditability, and decentralization, not as idealism, but as realism. The true protection of data in an entropic world lies not in stronger locks, but in better structures of shared stewardship.

2.3 EMBODIMENT

“To interact is to change, and to change is to exist.”

Information is not simply an external resource, it is a living force that evolves through interaction. Once information floods the landscape, value emerges only where an agent focuses. Embodiment is the intersection of pattern, scale, and intention.

We often imagine information as static or objective, but its significance depends entirely on the lens through which it is perceived. The present moment becomes the stage on which meaning is made. Like a vector, every life has both direction and magnitude, but awareness exists only at the point of observation. Life, and thus knowledge, is experienced as a succession of changes within this focal point of attention.

Zooming Zooming in on data reveals structures that vanish at broader scales; zooming out uncovers patterns that overwhelm the details. This fractal property of information means that discovery is not just a matter of scale or novelty, but of lens and arrangement. Systems must therefore record not just data, but the interpretive frame through which it was captured.

Across scales, from electrons to ecosystems, the same relational logic holds. As above, so below: the spin of a particle and the spin of a gear follow the same patterns of interlock and rhythm. Semantic consistency across these scales suggests a universality that Mycite encodes, allowing a single framework to traverse domains as diverse as neuroscience, urban planning, and language.

The rise of personal AI tools brings this challenge to the fore. Automation increasingly performs the work of generation. But meaning-making remains a human task. The future belongs to curators; those who choose, arrange, and present data with care and perspective. Tools extend embodiment, but do not replace it. They shift labor from creation to interpretation, demanding systems that reward context, not just output.

Translation further reveals this demand. Meaning often degrades when transferred across media or modality. Mycite addresses this by preserving the coordinate grammar; the semantic logic of how meaning was arranged and observed. It ensures that whether a message is seen by a human or an algorithm, its original structure and viewpoint remain legible.

With Conservation, Entropy, and Embodiment in place, we can now examine how legacy systems ignore these principles and how Mycite leverages them.

3. PROBLEM

The systems we have built around digital information are collapsing under the weight of their contradictions. At their core, these systems are structured on the illusion that information can be contained, owned, or permanently restricted. Instead of adapting to the true nature of information, they rely on increasingly brittle controls;

encryption, legal silencing, and centralized access; that are quickly becoming unsustainable.

This failure is not technical alone, it is philosophical. Attempts to monetize information through ownership presume a kind of scarcity that information does not possess. Unlike finite goods, information spreads and multiplies upon contact. When economic models treat it as a commodity to be hoarded, the result is not only inefficiency, but harm. Closed platforms, proprietary formats, and user surveillance are not side effects. They are necessary consequences of a system trying to contain the uncontainable.

What we face now is not just systemic risk, but moral decay. The burden of security is placed on individuals who are neither equipped nor empowered to defend themselves. Users are blamed for breaches, fined for circumvention, and penalized for seeking transparency. All while corporations consolidate control, obfuscate accountability, and privatize access to knowledge. This imbalance is unsustainable and unethical.

Without acknowledging the impossibility of owning information, every attempt to govern digital space becomes a performance of control rather than a practice of care. Law becomes weaponized, trust becomes transactional, and innovation becomes exploitative. The more we enforce ownership, the more fragile our institutions become.

The Mycite Project stands in direct opposition to this trajectory. It calls for a fundamental declaration: information cannot be owned. This is not a rejection of privacy, authorship, or credit, but a rejection of structural hoarding and digital feudalism. From this declaration follows a necessary redesign: one that treats information systems as stewards of flow and contribution, not gatekeepers of value. The remainder of this report explores how such systems can be designed, governed, and sustained.

3.1 ECONOMICS

Value in a digital society cannot be priced as if it were grain or gold. Classical economics linked price to scarcity: land, labour, raw material. Scarcity economics breaks down for information, by contrast, as digital artefacts are infinitely replicable. Licensing, DRM and patent fences merely simulate scarcity as a distortion of what is reality. This model was fine for a time, as we wish to reward those that contribute, but as this underlying idea erodes, so do many other institutional operations.

Information breaks the four-goods box. Public, private, club and common goods are defined by rivalry and excludability. Information is naturally non-rival (my use leaves yours intact) and non-excludable unless we add artificial gates. It behaves more like a semantic commons: value is created when people arrange, interpret and recombine shared meaning.

Misaligned Incentives of “Ownership” are rising to the surface of public discourse in conversation about the student-debt model. Tuition is priced as though universities could repossess knowledge if payment lapses. Once learned, however, knowledge lives with the student. Like eyeglasses that permanently sharpen vision after purchase. The result is economic drag: lenders extract rents from a resource that no longer exists as a scarce asset. These Lock-in models try to reclaim perpetual value from knowledge that cannot be repossessed, leading to economic and moral inefficiency.

Automation amplifies this distortion. If proprietary AI platforms lease the “software brains” that run factory robots, one vendor can steer an entire national workforce and govern an entire labor market even when citizens “own” the hardware. Safety regulation for self-driving cars and drones makes this monopoly path politically tempting unless open standards intervene.

Orchestration, not ownership, creates Impact. Economic value in the information age arises from time, insight, raw materials and energy, not from hoarding bit-patterns. Mycite proposes a contribution-first accounting layer that measures who arranged what, when, and for whom, rewarding orchestration over exclusion. It lends itself to only an empirical defense of information being structured so that there is no question of what it is and how it exists. This does not prevent identity, merely leaves as the sole responsibility for those that wish to govern a system of trust, with no control over the free flow of information. A live prototype of how this might work is seen in Barcelona’s Fab-City. The city’s “locally productive, globally connected” programme routes digital design files through open Fab Labs while sourcing material nearby. The payoff: reduced waste of material, reduced waste in energy, resilient supply chains and community-level innovation. It proves that open design + local fabrication can out-compete linear, ownership-centric supply chains.

Transition is inevitable. Failing to adapt courts systemic risk. If society clings to information ownership while local fabrication and AI march on, we’ll be blindsided by power concentration and missed ecological/innovation gains. Local manufacturing and ubiquitous AI are coming, with or without new rules. Clinging to proprietary control will centralise power, stifle participation and leave societies unprepared for a world where anyone can fabricate almost anything. Embracing a contribution economy now (through frameworks like Mycite) lets us capture the upside while distributing agency.

Scarcity logic made sense for grain and gold. In an era of recombinant code and local fabrication, prosperity flows to systems that coordinate contribution rather than gatekeeper copies; but information doesn’t fit the four standard goods classes as it is naturally non-rivalrous and non-excludable. I behave more like a shared semantic commons than a private, club, public, or common good.

3.2 TRUST

Trust is the substrate of any society. When the flow of information becomes the basis for identity, coordination, and agency, trust is no longer a social courtesy. It is infrastructure. But today's systems have built that infrastructure on a paradox: they ask users to trust systems they cannot see, while holding them accountable for outcomes they cannot control. If those channels are opaque, society’s foundation rests on blind faith. Certifications, marketing, and compliance badges simulate assurance; without verifiability they amount to coercion.

The opacity paradox has established modern devices to ship to consumers with closed-source software, proprietary firmware, and black-box algorithms. Users must “agree” to unseen code, yet are those that are burdened when systems fail. Users are seen as

individuals who knowingly risk their data's privacy, simultaneously, these applications and devices are privately owned, and are not responsible for any level of tailored function despite or open to audit. Meanwhile people are left without alternative options to compete in today's world and choose to be responsible to keep their information from risk. When that code leaks passwords, deepfakes their likeness, or locks a bank account its seen security is promised but unverifiable.

- Data-breach settlements compensate for companies' reputational loss; victims still repair credit for years.
- Reverse-engineering to audit risks is criminalised, insulating vendors from scrutiny.
- Alternate apps are disabled or declared "insecure," leaving no functional exit.

Liability is deliberately misallocated. Corporations harvest data and externalise risk (breaches, fraud) while outlawing scrutiny and blocking alternatives. When they do suffer consequences it is seen as a payment to do business, not as a punishment. Corporations monetise personal data while externalising fallout. From phishing to identity fraud, users absorb the damage, courts accept digital logs as character evidence, and social-security numbers remain the brittle master key. In practice, we "own" devices in name only. What this puts on display is a system that is not called into question on the basis that it collects our information, it calls into question a complete lack of choice to avoid risks. It will continue to be more difficult to prevent the spread of our data, and so the flaw is that this is capable of being a risk.

As a society continues to avoid rethinking its ownership of information, in place of new systems, companies will continue to rise to the task of confirming a person's identity and what is true and what is not. A people's only option being the use of those same companies for live verification codes to enable our access to invaluable digital resources, even our banks, health records, and taxes. Opaque control endangers democratic self-determination. When a handful of vendors or agencies arbitrate "who you are" and "what is true," civic power shifts from people to gatekeepers. This is unavoidable, in the form of companies or governments. It merely poses the question how we might decentralise this identity and system of trust. Verifiable, distributed trust demands open, local, interoperable tools. Mycite proposes such tools, treating information as unownable and pushing custody/inspection to the edge rather than the centre.

3.3 TUST-LESS

Systems built on "ownership of information" will break, not bend. The assumption of information ownership has driven the design of both legacy institutions and emerging technologies, but neither can escape the consequences of building on a false foundation. Whether enforced through legal mechanisms, cryptographic walls, or proprietary ecosystems, the result is the same: fragility, centralization, and eventual collapse.

Consider Bitcoin's proof-of-work ledger. It was designed as a decentralized alternative to institutional finance; a 'trustless' collaborative network. Claims of certainty assert that ownership does not need to be trusted or not trusted, it can just be certain. Currency outside state control. But by embedding its use in decentralization and proof-of-work mechanisms, it enshrines informational rigidity. It is a known fact that crypto-currencies, without having a central authority to update its manner of encryption, will inevitably fail. This is the case even without quantum computing on the rise. Bitcoin exposes the paradox of trying to decentralize while still clinging to ownership logic: the ledger is open, but control is rooted in accumulation and exclusivity and like all systems based on encryption, without a central authority to update its operations, it will fail. Not to mention its spiraling energy consumption, risk of a 51% attack and volatility.

Ethereum, in contrast, has avoided collapse by pivoting toward centralized coordination. Despite being marketed as a decentralized platform, Ethereum depends on core teams, curated updates, and emergent hierarchies to maintain momentum. Its resilience is not proof of decentralization, but of the implicit re-centralization needed to stabilize systems that attempt to own programmable logic. It has become just another privatized fiat-currency, like flight reward points. Not that there isn't value in either but rather they don't represent what people think.

True decentralization within a trustless network hinges on prioritizing information credit rather than ownership proof. Consequently, blockchain becomes truly advantageous when employed by localized democratic communities to validate credited information. This approach maximizes blockchain functionality and ensures sustained use, but requires a small trusted group for centralized control. Paradoxically, attempting to decentralize information ownership without centralizing control results in either unsustainable outcomes or a false sense of autonomy. These insights reveal the limitations of models that overlook this fundamental relationship. Furthermore, this framework can be scaled to represent a state ledger aggregating county contributions into a national ledger. Similarly, private sector companies, churches, schools, or the creation of an inheritance-based digital research database can benefit from this model.

This may end up with national connected networks typically aggregating trust ledgers from immediate levels below, like states collecting data from counties or cities. While an internet without strict identity control is possible, there's a demand for a unified communication system founded on individual connections. This structure would restore journalism's utility, as news becomes meaningless without it. Implementing this is challenging, so the Mycite Project aims for a hyper-extensible system, based on technically enforceable and socially distributed trust. That means building tools that are:

- **Open by default, so behavior can be inspected and improved by anyone.**
- **Interoperable by design, so no single vendor can monopolize access.**
- **Locals in custody, so individuals retain sovereignty over the data they use to inform decisions at the very least.**
- **Semanticly designed so that the framework never falls out of date, only the implementation.**
- **Allow for central authorities to be broken up into layers for needed updates and changes.**

Instead of striving for a trustless Web 3.0, like earlier efforts, the Mycite system focuses on information as it exists, without prioritizing ownership. This approach achieves genuine trustlessness: information is definitively what it is underwood to represent. Actions of navigating, mediating, referencing, and manipulating information

are not put at risk of mismanagement only vulnerable to falsity that a person chooses to push. Even then for application such a research, references can inherit true references that don't have the ability to represent anything but what they represent.

3.4 TECHNOLOGY & POWER

As outlined in the introduction of this report, every wave centralises before it cracks. AI and cryptography are the latest posts now constricting growth. Technology is not neutral, it is an amplifier. It does not create power, but redistributes and concentrates it. Every technological shift in human history has changed who holds power, how it's exercised, and what forms of governance can persist. And each time, those unwilling to adapt have been swept away.

The agricultural revolution allowed a few to feed many, enabling cities, states, and kings. The printing press shattered the monopoly on scripture and sparked the Reformation. The internet replaced gatekeepers with hyperlinks. And now, artificial intelligence, cryptography, and quantum computing are collapsing the remaining boundaries around knowledge and coordination.

Each of these waves increased the total power available to society. power to act, to know, to influence. But this growth is not linear, and neither are its social consequences. When the distribution of power diverges too far from the systems designed to manage it, a tipping point is reached. Systems centralize, resist, or collapse.

Historically, the beneficiaries of each wave built new institutions to preserve their advantage. Universities rose after literacy spread. Broadcast empires ruled the airwaves. Today, tech monopolies govern our data and devices. But the cycle always turns. Individuals can now create what once required teams; organize without hierarchies; build systems without permission.

This shift demands a new model of coordination. One that does not attempt to reclaim control through digital empires, but distributes capability through digital commons. Mycite sees this not as a challenge to governance, but a call to redesign it. The tools of today allow for coordination at scale without centralization. If the systems we build are aligned with the properties of the tools themselves.

Technology's momentum cannot be paused. But it can be steered. And whether that momentum leads to collapse, coercion, or collective stewardship depends entirely on whether we embrace the redistribution it demands.

3.6 CRITICAL POINTS

History doesn't just repeat, it compounds. Each new tool, system, or idea adds to the cumulative complexity of society. Over time, these layers reach a breaking point, where the assumptions that once held society together begin to tear it apart. We are living through one of those critical transitions now.

From education to economics, from governance to media, institutions built for a world of scarce information are straining under its abundance. Systems that once relied on centralized control, secrecy, and hierarchy are colliding with a public that can search, synthesize, and self-organize in real time. As a result, the gatekeepers are doubling down, fortifying walls, tightening laws, hoarding access.

But the pressure cannot be contained indefinitely. The more power becomes concentrated without consent, the greater the risk of collapse or authoritarian control. These are not conspiracy theories; they are historically recurring outcomes when institutions attempt to preserve power through force rather than reform.

The transition we face is not optional, it is structural. Either we distribute power with intention, or it redistributes itself through upheaval. The good news is that we now have tools to make that transition peaceful and productive. We can design systems that scale cooperation without centralization. But doing so requires rejecting the mental model of ownership, and the institutional reflexes that come with it.

The Mycite Project identifies this inflection point not just as a risk, but as a chance. A rare historical window in which a better system can be built, not imposed, but adopted. Not enforced, but trusted. Not sold, but shared.

This is not a call for revolution, but for renovation. The walls are already cracking. We simply propose building exits before they fall.

4. SOLUTION

The collapse of ownership-based information structures isn't merely a technical inconvenience; it's a coordination failure that threatens social cohesion, economic stability, and informational trust. The Mycite Framework was developed to offer not just a technical patch, but a reimagined way of engaging with data that respects entropy, context, and autonomy.

4.1 THE MYCITE FRAMEWORK

Local Use Case: The Framework as a Tool for Individuals or Organizations; the Mycite Framework can serve individuals or institutions seeking to manage dynamic data with high fidelity and ethical integrity. Within a design studio, for instance, Mycite can map creative focus, track process outcomes, and ensure consistent semantic feedback between clients, projects, and production tools. All without surrendering control to a third-party platform.

Every directive becomes a piece of context-rich intent, not a locked-down transaction. Data navigation becomes a dialogue rather than a command prompt. This enables greater modularity, auditability, and adaptability.

4.1.1 The Control Gate Design:

At the heart of Mycite is the Control Gate. A system design framework that operates less like a program and more like a decision-making process. It does not control information, but mediates between attention, intention, and context. By reflecting the user's focus, goals, and semantic orientation in real time, it allows digital systems to act more like collaborative tools than command hierarchies.

The Control Gate simulates the layered nature of human decision-making by prioritizing context over commands. Events are

parsed into four categories: Navigation, Investigation, Manipulation, and Mediation. Then those events are dispatched to update system state based on their context and significance. Asynchronous signals are harmonized through a single cognitive loop that preserves meaning while adapting to change.

This architecture allows for:

- Real-time updates to system state from asynchronous inputs.
- Intent classification that preserves semantic relevance.
- Reflection of decision-making logic directly in application behavior.

By mirroring cognitive attention systems and filtering updates based on contextual thresholds, Control Gate enables systems that feel cooperative rather than deterministic.

~~~
~~~

Location = Fully qualified reference path Atomic Resolution = Conventionally-resolved interpretation layer
A table's name serves as part of the "address space", almost like a namespace or type anchor.
Instances inside the table are instances of the archetype implied by that table's definition.
Tables may reference other tables (via name or address) in order to inherit or constrain their own archetype.
And crucially: No central rigid hierarchy is imposed. Relationships emerge from how tables reference each other via these addresses.

4.2 IMPLEMENTATION ENTRY POINT

Agriculture is the ideal proving ground: it combines a coordination problem that does not allow for vertical expansion in that the value it provides is its individually cared for and locally produced food, but it can not adopt the benefit of horizontally grown service companies, like shipping and delivery companies, for use as they are not able to access the fragmented industry as a single resource. So without making small-sustainable-local agriculture give up their independence we can provide software applications that are open source, with tools and interfaces customized to their needs, by entering into contract revenue agreements that allot a percentage within some physical period. These applications can be in support of personal website management, using the personal website to as their point of financing with farmers market websites, community service agriculture, or specialty grocery store website; allowing shipping invoices, order, and all other invoice and inventory data to be a part of their management suite. Allowing individuals or companies to employ inhouse Enterprise Resource Planning on their in house 'data-base' that other applications can be built on to use. Currently small business and self incorporated individuals only have the option to use many different softwares that are disjointed and do not work together, SaaS services with compounding subscription fees, or get custom development that is out of their price range. In this way, their software and hardware can be serviced as if it were a car, by any contractor that builds on this semantic web framework. Additionally any industry party can develop applications that users can interact with through their own personal websites as their profiles, allowing for the aggregation and curation of information and not disjointed hosting.

If small-sustainable-local agriculture could match the 25% greater agricultural output with respect to perishable crop output per acre (not efficiency in growth) compared to their industrial counterparts. An estimated 70 billion dollars in waste could be kept from leaking out of local economies in the US. In Ohio alone 700 million is estimated to be lost each year as a result of this fractured network. In 12 north east Ohio counties an approximate 28 million dollars could be reclaimed, purely by allowing these decentralized networks to work into a seamless network of information, and closing the gap of who, what, when, where, and how an area is in supply and respectively in demand.

Mycite empowers farmers to:

- Define and manage their own schema of operation.
- Share insights across co-ops or regional networks without risking central lock-in.
- Contract engineering support (e.g., via Fruitful Network Development) on a modular, competitive basis. Building an ecosystem where tools serve people, not platforms.

4.6 MISSION ROAD MAP

To navigate deployment, support, and growth; the Mycite Project's ongoing mission intends to:

- Deploy early-stage implementations with farming collectives.
- Develop and share free, modular toolkits built atop Control Gate and MSS.
- Serve as a public steward of these standards, not a gatekeeper, but a model of sustainable alignment.
- Apply for USDA alignment grant

The long-term goal is to establish a cooperative software industry that scales the values of trust, clarity, and interpretability. Mycite is a blueprint for how we can move past the illusion of ownership and into an era of contributive digital agency.

5. CONCLUSION

[Discussion Here; about how this and why this reality calls for a new path forward and why the solution provided is the best path. Also discusses how the Mycite project aims to develop awareness of these issues, and after developing the industry the mission driven effort aims to create an s-corp artificial intelligence company that serves to propagate a collective consciousness, rather than an owned product. Perhaps also discussing effort to establish state level agencies to help integrate digital rights and services]

6. EXTENDED DISCUSSION

[Discussion Here]

6.1.7 Industry Union:
[Discussion Here]

6.1.8 Automation:
[Discussion Here]

6.2 DEVELOPMENT DISCUSSION

[Leading Paragraph Here]

6.2.1 Jumpsets & Optimization:

Jump sets and Optimization:
To address potential resolution bottlenecks or high-cardinality domains, MSS introduces Jump Sets: pre-computed sets of often-used domain references. These allow address resolution to shortcut through a curated space of frequently meaningful relationships.

Jump Sets are used:

- To reduce computational overhead.
- To cluster related values for faster interpretation.
- As a fallback heuristic when meaning is ambiguous or partial.

6.2.1 Extensability:

The Mycite Framework is designed with extensibility as a primary goal:

- Modular plugins for additional archetypes or schema types.
- Interface abstraction layers (e.g., CLI via Hyphae, visual interface via Bloom).
- Real-time input/output orchestration through asynchronous streams.

These design principles enable future expansions into new media types, automation contexts, or network-based multi-node environments.

6.3 SYSTEM LANGUAGE

6.3.1 Term Definitions:

Differintegrality (noun)

- Mathematics. The dual character of a quantity or system when viewed simultaneously through its differential (rate-of-change) and integral (accumulated-effect) lenses.
- The continuum that links differentiation and integration, treating them as inverse aspects of a single calculus operation rather than separate procedures.

[By extension. Any analytic stance that holds instantaneity and accumulation in a single conceptual frame. For example, monitoring the “differintegrality” of economic data (instant growth vs. total output) or signal processing (instantaneous frequency vs. cumulative phase).]

Usage notes:

- Differintegral (adj./n.): relating to or embodying differintegrality.
- Coined to serve the same role for derivative ↔ integral that polarity serves for positive ↔ negative.

Example:

- “In ecosystem modeling we track the differintegrality of nutrient flow, capturing both the instantaneous uptake rates (differential view) and the season-long storage totals (integral view).”
- This definition lets you invoke differintegrality whenever you want to emphasize that a value’s meaning emerges only when its derivative and integral aspects are considered together.

Code - A system that establishes a one-to-one functional relationship between two distinct, finite sets of elements.

- E.g. given the assignment {Y = 4, O = ★, U = #}, then the sequence '4★#' is equivalent to 'YOU'.

Encryption - The process of converting a set of original data elements into a new, related set. This transformation uses mathematical and algorithmic logic, where numerical values from the original data guide a unique conversion process.

First order Elements - The most adjacently visible form of what makes up the sum of what is an instance of information.

- E.g. A visible view of a display screen might be considered an instance that is made up of pixels, made up of the RGB lights that make up those pixels (lessened abstraction), or it may be considered a top level topic of display that is made up of information like text and pictures.

View Value - A value that relates to the size of a space.

Focus Value - A value that relates to the magnitude of deviation of 1 space.

Field-Archetype - A denoted model that represents the value for which an instance can be a representation of a certain type.

- E.g. An instance of which has a View-value of 10,000 and a Focus-Value of 3 can be used to describe an instance of 30,000 first order elements

Babel Address - Denotes the predetermined value of each first order element for an instance of a Field-Archetype class, by having all possible instances of an Field-Archetype (given a first order element) ordered by the exponential operation of change of the first order elements (Bound by its possible values).
