# INFORMATION TECHNOLOGY SOCIAL SYSTEMS: THE MYCITE PROJECT, WHAT IS AT RISK, MITIGATING HARM, VALUE PROPOSITION, & WHAT IS BEING DONE

AUTHORED BY: DYLAN MONTGOMERY

## ABSTRACT

The Mycite Project is a mission-driven effort to support public awareness of systemic information problems and to develop the Mycite Framework Technology as a solution. This report outlines the need to establish a new foundation for the information technology industry. One that recognizes the impossibility of information ownership, addresses the threats posed by continued adherence to outdated models, and proposes a decentralized, standards-based system for the ethical and resilient use of information.

## 1. INTRODUCTION

In the modern world, our lives are shaped by systems built around a dangerous misconception: that information can be owned. This fallacy underpins digital economies, surveillance regimes, and power structures that are rapidly becoming incompatible with the reality of technological progress. At the same time, quantum computing, artificial intelligence, and networked digital tools are accelerating the collapse of these systems from within. Societies face a binary illusion: either cling to failing structures until collapse, or tighten control through surveillance and digital authoritarianism. Yet a third option exists. One that demands new assumptions, new governance, and a new digital infrastructure.

The Mycite Project is a response to this moment. It is grounded in the view that our social systems must transition from containment-based models of information control to contribution-based models of interaction. This shift is both moral and practical. Just as energy cannot be owned, only harnessed and directed, so too is information a force of nature; subject to entropy, recombination, and discovery. The question is not whether this transformation is coming, but whether we will meet it with foresight or be overtaken by crisis.

## 2. BACKGROUND

The study of Surrealmatics [*the philosophical and technical understanding of information as a natural force*] offers a critical lens for interpreting the present. Information exhibits characteristics analogous to physical forces: entropy, momentum, semantic density, and recursive structure. These traits reveal why the traditional model of ownership is not just impractical, but incompatible with the behavior of information itself.

Information, like energy, flows and disperses. Its value is not static, but created through intentional arrangement. As AI systems show, “creation” is merely the recombination of known elements into new arrangements. In a finite digital universe, such as all possible strings of a given character set, novelty is not invention, but discovery. As systems like language models traverse these possibility spaces, they blur the lines between author and algorithm, creator and tool.

At the same time, information is becoming denser and more accessible. Each discovery adds to a collective field of knowledge, accelerating our ability to build on prior work. Like a fractal, new truths emerge from recursive refinement, whether through deep, focused analysis or broad, high-level synthesis. This scaling behavior collapses traditional hierarchies of expertise and ownership, placing greater value on contribution, intentionality, and perspective.

Understanding these dynamics is essential. As with the physical world, ignoring the natural properties of a system does not prevent its consequences, it only increases their severity. The remainder of this report will examine the systems currently built on false premises of information ownership, the dangers they now pose, and the third-way alternative enabled by the Mycite Framework and its application in local, decentralized systems like agriculture.

### 2.1 INTENTION

The boundary between invention and discovery has eroded. This erosion is not a side effect of artificial intelligence but rather a revelation made clear. It compels us to reconsider what it means to create when all possible arrangements of information already exist in a definable space. A thousand-character page, for instance, composed from a set of 29 characters (letters, space, punctuation), has a finite number of permutations. Though vast, that space is not infinite. It is mappable. In this context, AI does not invent. It navigates.

When we understand content as instances drawn from a larger field of possibilities, originality becomes a matter of intention and selection rather than exclusive creation. The act of choosing, interpreting, and arranging from a field of known components is what we value. Not the false notion that such arrangements can be owned.

The implications extend beyond AI and into all domains where creativity is celebrated and monetized. As machines outperform humans in navigating and rearranging data, our economy must shift from rewarding novelty of output to rewarding novelty of perspective. The artist, the thinker, the builder; they contribute not because their elements are new, but because their arrangement says something real.

In the end, intentionality is what grants meaning to arrangement. It is the force that transforms permutation into expression. Our systems must be redesigned to value and protect intention, not to imprison expression in cages of artificial ownership.

### 2.2 ENTROPY

Entropy is the foundational principle that explains why information cannot be contained. It is  a natural law of information that governs digital systems. Like energy in traditional physics tends to move from a confined system, information tends toward proliferation. Information can not sustainably exist at the same time be kept from escaping any isolation. Attempts to resist this behavior through secrecy, encryption, or restriction are ultimately temporary, brittle, and destined to prolong the inevitable.

Today, digital infrastructure relies on encryption to enforce boundaries. Simply put, it allows points of contact to identify themselves across public lines of communication to establish a connection that is highly obfuscated. In essence, mathematical protocols are relied on to assume that a party is who they say they are and they are the only ones to be able to read information sent. These protocols work not by stopping information from spreading, but by obscuring it in such a way that only the right recipient can decipher it. Yet this fragile control mechanism faces extinction in the era of quantum computing. Despite the proposition of possible encryption methods that could solve shortcomings, in short, quantum computers will be capable of breaking the very foundations of our current encryption model.

There are already massive operations by capturing and storing encrypted data, with the assumption that in the near future it will all be easily deciphered.

Recently, its been observed, the leaps forward in sensory interfacing. By examining the pattern in across different images being shown to a subject and how they align or differ based on the images stimulation in the brain; scientist have shown proof of concept in an ability to make sense of the current attention of a subject's brain, with out ever having to know the complexities of how it works.

Furthermore, in recent years we have seen the unmanageable task of enforcing piracy laws. It is understood that if information is being transmitted to a personal device, that it can be captured. In response, large tech companies have employed restrictions on the devices that we use, under the guise that we do not own the software that operates them. Making it illegal to reverse engineer, what is in essence, a pattern of electrons that makes our devices work. As this pattern continues we will see centralization continue to be favoured as it is no leap in logic that we wish to have an economic system that rewards people's new ideas and effort to bring them about. However the flaw in this, is that it assumes that there is no other way to achieve this ideal.

This is not a purely technical problem, it is social, legal, and ethical. Systems today outsource liability for breaches to individuals, expecting users to defend themselves within infrastructures they cannot inspect or control. From massive data leaks to the criminalization of reverse engineering, our systems blame the user while protecting the opaque logic of closed software and proprietary design.

But entropy cannot be negotiated with. It is only by aligning with its inevitability that we can build resilient systems. This means shifting from an ethos of containment to one of coordination. Instead of locking data away, we must design systems that embrace openness, auditability, and decentralization, not as idealism, but as realism. The true protection of data in an entropic world lies not in stronger locks, but in better structures of shared stewardship.

### 2.3 EMBODIMENT

Information is not simply an external resource, it is a living force that evolves through interaction. Like a fractal, information exhibits recursive depth: zooming in reveals new structures, while zooming out reveals larger patterns made from the same essential elements. This means that discovery is not just a function of scale or novelty, but of perspective and arrangement. The same energy, applied with focus or breadth, can yield insight, depending on the structure of what's observed.

As technologies increase our capacity to perceive, interpret, and manipulate information, we must recognize that all new knowledge is fundamentally a rearrangement of what is already known. This is not a limitation, but a powerful principle. Just as atoms are reused endlessly in nature, ideas recombine endlessly in culture. The process of knowledge creation is an act of recombinative embodiment; transforming existing informational components into meaningful new constructs.

This realization has profound implications. It means that intelligence, whether artificial or human, is not a source of spontaneous originality but a filter of meaningful rearrangement. The value of a contribution is measured not by its raw materials but by the intentional synthesis of structure and context. As information becomes denser, the opportunity space for meaningful discovery grows. Not linearly, but exponentially.

Yet our systems still attempt to define ownership over these rearrangements, denying others the right to interpret or reuse what has been structured. This is the embodiment of a false scarcity. A refusal to acknowledge that meaning emerges not from exclusivity but from accessibility.

The Mycite Project views embodiment as the living intersection between individual intention and the shared informational substrate of the world. It is this interface; between the internal and the external, the focused and the expansive; that must be supported by future systems. When we support individuals not by gating access, but by enabling expression and interpretation, we align our tools with the nature of information itself.

## 3. PROBLEM

The systems we have built around digital information are collapsing under the weight of their contradictions. At their core, these systems are structured on the illusion that information can be contained, owned, or permanently restricted. Instead of adapting to the true nature of information, they rely on increasingly brittle controls; encryption, legal silencing, and centralized access; that are quickly becoming unsustainable.

This failure is not technical alone, it is philosophical. Attempts to monetize information through ownership presume a kind of scarcity that information does not possess. Unlike finite goods, information spreads and multiplies upon contact. When economic models treat it

as a commodity to be hoarded, the result is not only inefficiency, but harm. Closed platforms, proprietary formats, and user surveillance are not side effects. They are necessary consequences of a system trying to contain the uncontainable.

What we face now is not just systemic risk, but moral decay. The burden of security is placed on individuals who are neither equipped nor empowered to defend themselves. Users are blamed for breaches, fined for circumvention, and penalized for seeking transparency. All while corporations consolidate control, obfuscate accountability, and privatize access to knowledge. This imbalance is unsustainable and unethical.

Without acknowledging the impossibility of owning information, every attempt to govern digital space becomes a performance of control rather than a practice of care. Law becomes weaponized, trust becomes transactional, and innovation becomes exploitative. The more we enforce ownership, the more fragile our institutions become.

The Mycite Project stands in direct opposition to this trajectory. It calls for a fundamental declaration: information cannot be owned. This is not a rejection of privacy, authorship, or credit, but a rejection of structural hoarding and digital feudalism. From this declaration follows a necessary redesign: one that treats information systems as stewards of flow and contribution, not gatekeepers of value. The remainder of this report explores how such systems can be designed, governed, and sustained.

## 3.1 ECONOMICS

Economics is the lens through which society assigns value. Historically, value was attached to scarce resources: land, labor, raw materials. As we transitioned into the information age, scarcity became simulated. Digital products, infinitely replicable, were made artificially rare through licensing, encryption, and legal ownership claims. But the core problem remains: information does not obey the rules of commodity economics.

To reconcile this, we must rethink our classifications. Goods have traditionally fallen into four categories: public, private, club, and common. Information resists all of them. It is non-rivalrous (your use doesn’t diminish mine) and non-excludable unless artificially constrained. In reality, information is closer to a semantic commons; shared, shaped, and recombined across society.

Attempts to treat information as private property lead to misaligned incentives. Consider student debt. It is often structured on the presumption that future income is a direct result of institutional knowledge transfer. But knowledge, once acquired, cannot be un-learned or repossessed. Its value is realized only through further arrangement and contribution. Just as selling someone eyeglasses does not entitle the seller to a share of future earnings enabled by better vision, facilitating access to information is a service, not a stake in output.

Further more is how we might consider the proliferation of using robots in the work force. If software and AI companies operate as they do now, it is clear how in order to stay competitive in price and quality, even small businesses will eventually utilize robots in a work force. Thus, in this model it is possible that a single company can be at the helm of an entire nation's work force, despite people owning the hardware. This is a natural playout of events as rising concern for safety is an ever present topic in regards to self driving cars and drones. Why would a people’s nation choose another option that does not prevent them from staying competitive on the world stage, as well as one that mitigates similar concern for harm to that of personal firearms.

The Mycite Project asserts this third path, not as a demand, but as a suggestion and an option. With a mission to create the social fabric that peacefully allows for a transition to information holding an economic value that doesn't rapidly degenerate choice and power being held by a central authority. It is not ownership but orchestration that creates impact. Economies that value time, novelty, insight, raw materials, and energy, are better aligned with the properties of the digital age.

This transition is already underway with the rise of fabrication labs. These laboratories are an advancement in taking away and adding material, in ever greater complexity and detail. Barcelona. for example, and its initiative to become a zero import, zero export city is rooted in its pioneering Fab City strategy, launched from the Institute for Advanced Architecture of Catalonia (IAAC) and the global Fab Lab network. The city envisions transforming from a linear consumer of global goods into a locally productive, globally connected hub. One where materials are sourced and goods are fabricated locally in digital fabrication labs (Fab Labs), while only digital data (like design files) is imported or exported. By investing in public maker spaces, educational programs, open-source tools, and urban manufacturing policies, Barcelona is creating infrastructure that enables neighborhoods to meet many of their own material needs. This approach demonstrates that any city; with a commitment to open knowledge, community-led innovation, and decentralized production; can feasibly adapt the Fab City model to build local resilience, reduce environmental impact, and democratize production.

The benefit of a local manufacturing avenue is clear, and also what is at risk of staving off if we fight to maintain social systems that cling to ownership of information. If we can assume local fabrication is inevitable, then we can see how a lack of social fabric ready to adopt a world that does not own information, leads us to be unprepared for the coming difficulties and avoidance of coming benefit. How would our current system adopt a globalized world that is also localized in function.

## 3.2 TRUST

Trust is the substrate of any society. When the flow of information becomes the basis for identity, coordination, and agency, trust is no longer a social courtesy. It is infrastructure. But today's systems have built that infrastructure on a paradox: they ask users to trust systems they cannot see, while holding them accountable for outcomes they cannot control.

Closed-source software, proprietary firmware, and black-box algorithms dominate the modern landscape. Users are routinely asked to accept terms without knowing what data is collected, how it is processed, or whether it is sold. Security is promised, but unverifiable. And when breaches occur, the burden falls squarely on

the individual. From phishing attacks to data leaks to identity fraud, it is users, not system architects, who suffer the consequences.

This is not a minor oversight. It is a deliberate misplacement of liability. Corporations build infrastructures that extract and monetize user data, yet insulate themselves from the fallout. Reverse-engineering to investigate risks is criminalized. Transparency is discouraged. And alternative software is rendered incompatible or insecure through design. In effect, users “own” their devices in name only and have no choice other than to employ the use of digital services that freely collect their data. The very same data that our social security identification numbers hinge on. Our money is accessed through. The same data that the U.S. 's court systems deem as viable evidence to support claims of our character and actions, and that can replicate a person’s image and voice to say or do anything on video.

What this puts on display is a system that is not called into question on the basis that it collects our information, it calls into question a complete lack of choice to avoid risks which will continue to grow in impeccable nature. As a society continues to avoid rethinking its ownership of information, in place of new systems, companies will rise to the task of confirming a person's identity and what is true and what is not. With security codes and pins, only their software can confirm you may access your bank account, that you did what you say you did, that you didn’t do what you say you didn’t, that you are who you say you are. This is unavoidable, in the form of companies or governments. How is it that a nation made for the people by the people; can continue in place of an authority that declares for a people who and what and how those people exist and what is true.

In such a system, trust becomes theater. It is performed through certifications, marketing, and compliance, not earned through transparency or interoperability. But trust without verifiability is not trust. It is coercion in disguise, and with the rise of incapability to discern what is true and what is false on the internet, it needs to be said that the bottom line of news and social media is that it is grass roots. For a nation to be able to trust a connected network feed, it can only very acknowledge that a State of The union is real. Then it becomes a responsibility to make sure that a county or city is in fact a place. There can still be an internet that doesn't require such a rigid hold on identity, only that there is a demand for a single option that upholds a line of communication, held together at the bottom by one person, knowing another. This is also the only structure in which journalism could ever be a useful tool again, any news, any message, it all disappears into meaninglessness without it. Now this is much more difficult to implement but in the meantime the Mycite Project plans to allow for a system that is hyper excusable and that requires no central authority to operate or update. It begins with the premise that trust must be technically enforceable and socially distributed. That means building tools that are:

- **Open by default, so behavior can be inspected and improved by anyone.**
- **Interoperable by design, so no single vendor can monopolize access.**
- **Locals in custody, so individuals retain sovereignty over the data they use to inform decisions at the very least.**
- **Semanticly designed so that the framework never falls out of date, only the implementation.**
- **No central authority is needed for updates and changes.**

In a Mycite-based system, rather than previous attempts to create the trustless Web 3.0, ownership is not prioritized and thus the trustless aspect of the technology becomes entirely true on the basis that information is what it is. Trust a picture is a picture and not a picture that is standardized for viewing that can be gamed to also carry a virus. Research is published based on university owned blockchains that use inheritance.

Isolated implementations of trust create a fabric. Not one authority.

## 3.3 TUSTLESS

When systems built on flawed premises are pushed to their limits, they do not bend. They break. The assumption of information ownership has driven the design of both legacy institutions and emerging technologies, but neither can escape the consequences of building on a false foundation. Whether enforced through legal mechanisms, cryptographic walls, or proprietary ecosystems, the result is the same: fragility, centralization, and eventual collapse.

Consider Bitcoin. It was designed as a decentralized alternative to institutional finance; a trustless currency outside state control. But by embedding its legitimacy in a fixed ledger and proof-of-work mechanism, it enshrines informational rigidity. Its energy consumption spirals, governance remains inertial, and consensus hardens into stagnation. Bitcoin exposes the paradox of trying to decentralize while still clinging to ownership logic: the ledger is open, but control is rooted in accumulation and exclusivity and like all systems based on an encryption, without a central authority to update its operations, it will fail.

Ethereum, in contrast, has avoided collapse by pivoting toward centralized coordination. Despite being marketed as a decentralized platform, Ethereum depends on core teams, curated updates, and emergent hierarchies to maintain momentum. Its resilience is not proof of decentralization, but of the implicit re-centralization needed to stabilize systems that attempt to own programmable logic.

Both models fail to realize the central insight: you cannot decentralize ownership of information without centralizing control less it is unsustainable or farce ‘autonomy’. True decentralization of a trustless network, at its core, can only arise from one that prioritizes information being credited not ownership being proven. Through this lens, blockchain is extremely beneficial, but only if localized democratic communities employ its use to confirm credited information. This takes full benefit of blockchains function, and prevents it from falling out of use. It can only be useful if it does not claim to ensure ownership, and it can only be sustainable if centralized by a small group that trusts each other. This can be extended to represent how a U.S. state could have a ledger of county contributions, that feed into a national ledger. This also can apply to private sector companies, churches, schools, or used to create the once dreamed research digital database that uses inheritance.

The Mycite Project is built to support this imagined solution and its inherent assumptions in practice. Designed to reflect contribution, not control. This is the only foundation stable enough to scale with the complexity of our future.

### 3.4 TECHNOLOGY & POWER

Technology is not neutral, it is an amplifier. It does not create power, but redistributes and concentrates it. Every technological shift in human history has changed who holds power, how it's exercised, and what forms of governance can persist. And each time, those unwilling to adapt have been swept away.

The agricultural revolution allowed a few to feed many, enabling cities, states, and kings. The printing press shattered the monopoly on scripture and sparked the Reformation. The internet replaced gatekeepers with hyperlinks. And now, artificial intelligence, cryptography, and quantum computing are collapsing the remaining boundaries around knowledge and coordination.

Each of these waves increased the total power available to society. power to act, to know, to influence. But this growth is not linear, and neither are its social consequences. When the distribution of power diverges too far from the systems designed to manage it, a tipping point is reached. Systems centralize, resist, or collapse.

Historically, the beneficiaries of each wave built new institutions to preserve their advantage. Universities rose after literacy spread. Broadcast empires ruled the airwaves. Today, tech monopolies govern our data and devices. But the cycle always turns. Individuals can now create what once required teams; organize without hierarchies; build systems without permission.

This shift demands a new model of coordination. One that does not attempt to reclaim control through digital empires, but distributes capability through digital commons. Mycite sees this not as a challenge to governance, but a call to redesign it. The tools of today allow for coordination at scale without centralization. If the systems we build are aligned with the properties of the tools themselves.

Technology’s momentum cannot be paused. But it can be steered. And whether that momentum leads to collapse, coercion, or collective stewardship depends entirely on whether we embrace the redistribution it demands.

### 3.6 CRITICAL POINTS

History doesn't just repeat, it compounds. Each new tool, system, or idea adds to the cumulative complexity of society. Over time, these layers reach a breaking point, where the assumptions that once held society together begin to tear it apart. We are living through one of those critical transitions now.

From education to economics, from governance to media, institutions built for a world of scarce information are straining under its abundance. Systems that once relied on centralized control, secrecy, and hierarchy are colliding with a public that can search, synthesize, and self-organize in real time. As a result, the gatekeepers are doubling down, fortifying walls, tightening laws, hoarding access.

But the pressure cannot be contained indefinitely. The more power becomes concentrated without consent, the greater the risk of collapse or authoritarian control. These are not conspiracy theories; they are historically recurring outcomes when institutions attempt to preserve power through force rather than reform.

The transition we face is not optional, it is structural. Either we distribute power with intention, or it redistributes itself through upheaval. The good news is that we now have tools to make that transition peaceful and productive. We can design systems that scale cooperation without centralization. But doing so requires rejecting the mental model of ownership, and the institutional reflexes that come with it.

The Mycite Project identifies this inflection point not just as a risk, but as a chance. A rare historical window in which a better system can be built, not imposed, but adopted. Not enforced, but trusted. Not sold, but shared.

This is not a call for revolution, but for renovation. The walls are already cracking. We simply propose building exits before they fall.

## 4. SOLUTION

The collapse of ownership-based information structures isn't merely a technical inconvenience; it's a coordination failure that threatens social cohesion, economic stability, and informational trust. The Mycite Framework was developed to offer not just a technical patch, but a reimagined way of engaging with data that respects entropy, context, and autonomy.

### 4.1 THE CONTROL GATE DESIGN

At the heart of Mycite is the Control Gate. A system design framework that operates less like a program and more like a decision-making process. It does not control information, but mediates between attention, intention, and context. By reflecting the user's focus, goals, and semantic orientation in real time, it allows digital systems to act more like collaborative tools than command hierarchies.

The Control Gate simulates the layered nature of human decision-making by prioritizing context over commands. Events are parsed into four categories: Navigation, Investigation, Manipulation, and Mediation. Then those events are dispatched to update system state based on their context and significance. Asynchronous signals are harmonized through a single cognitive loop that preserves meaning while adapting to change.

### 4.2 THE MYCELIUM SCHMEA STANDARDIZATION

The Mycelium Schema Standardization (MSS) is a new ontology of data that supports the Control Gate. This is a semantic address-space model where information is never “fixed” but always contextualized. Here, tables define domains, and domains define how to interpret references. Meaning is deferred through layers until resolved at an atomic domain via shared conventions.

This destroys the foundation for centralized ownership: value is no longer attached to files or instances but to interpretive paths. MSS is more than schema; it’s a living ontology for information, inherently structured for interoperability, decentralization, and clarity.

### 4.3 THE MYCITE FRAMEWORK

Local Use Case: The Framework as a Tool for Individuals or Organizations; the Mycite Framework can serve individuals or institutions seeking to manage dynamic data with high fidelity and ethical integrity. Within a design studio, for instance, Mycite can map creative focus, track process outcomes, and ensure consistent semantic feedback between clients, projects, and production tools. All without surrendering control to a third-party platform.

Every directive becomes a piece of context-rich intent, not a locked-down transaction. Data navigation becomes a dialogue rather than a command prompt. This enables greater modularity, auditability, and adaptability.

### 4.4 THE MYCELIUM NETWORK

Scaling to Networks: The Mycelium Network and Decentralized Interoperation. Beyond the single-user model, the Mycelium Network allows these systems to interoperate without resorting to central servers. Each node maintains its own schema instance, and interactions occur via agreed-upon domain resolutions. There is no central hub, only shared mappings.

Trust emerges not from encryption alone, but from visibility into context chains, resolution paths, and transformation flows. Just as language requires mutual understanding, Mycite frameworks synchronize not by force but by interpretive alignment.

### 4.5 THE IMPLEMENTATION ENTRY POINT

Agriculture is the ideal proving ground: it combines high-entropy coordination problems with low digital agency. Farmers manage complex systems of input, timing, and biological response, yet are often locked out of their own data by proprietary SaaS tools.

Mycite empowers farmers to:

- Define and manage their own schema of operation.
- Share insights across co-ops or regional networks without risking central lock-in.
- Contract engineering support (e.g., via Fruitful Network Development) on a modular, competitive basis—building an ecosystem where tools serve people, not platforms.

### 4.6 THE MISSION ROAD MAP

To navigate deployment, support, and growth; the Mycite Project's ongoing mission intends to:

- Deploy early-stage implementations with farming collectives.
- Develop and share free, modular toolkits built atop Control Gate and MSS.
- Serve as a public steward of these standards, not a gatekeeper, but a model of sustainable alignment.

The long-term goal is to establish a cooperative software industry that scales the values of trust, clarity, and interpretability. Mycite is a blueprint for how we can move past the illusion of ownership and into an era of contributive digital agency.

## 5. CONCLUSION

[Discussion Here; about how this and why this reality calls for a new path forward and why the solution provided is the best path. Also discusses how the Mycite project aims to develop awareness of these issues, and after developing the industry the mission driven effort aims to create an s-corp artificial intelligence company that serves to propagate a collective consciousness, rather than an owned product. Perhaps also discussing effort to establish state level agencies to help integrate digital rights and services]

## APPENDIX

### A. THE CONTROL GATE SYSTEM DESIGN

The Control Gate is the Mycite Framework's core control loop, acting as the synchronous center of a modular, intention-based program. It integrates user and system inputs by classifying them into four primary intent types: Navigation, Investigation, Manipulation, and Mediation. These are then dispatched through an interpreter to update the AppState, which represents the live contextual model of the system's current focus, visible structures, and linked meanings.

This architecture allows for:

- Real-time updates to system state from asynchronous inputs.
- Intent classification that preserves semantic relevance.
- Reflection of decision-making logic directly in application behavior.

By mirroring cognitive attention systems and filtering updates based on contextual thresholds, Control Gate enables systems that feel cooperative rather than deterministic.

## B. THE MYCELIUM SCHMA STANDARDIZATION

MSS defines a hierarchical, recursive schema system where each instance (or record) is interpreted through the lens of its domain. Domains themselves are tables, and values resolve downward toward an atomic domain—where interpretations follow conventional or symbolic meaning rules.

Key features include:

- Schema instances modeled as object-oriented entities.
- Address resolution through domain layering.
- Deferred meaning via semantic networks and interpreted relational paths.

This creates a stack of nested contexts, akin to a semantic address space. Meaning emerges not from static content, but from the resolved relationships of structure and context. MSS is thus a symbolic runtime for data meaning.

## C. DATA HANDLING ARCHITECTURE

- Peripheral Modules: StateReadIn, StateReadOut, MyciteReadIn, MyciteReadOut allow for modular integration of user, device, and network I/O.
- AppState: Maintains the live state of attention, view, earshot, and queued intentions.
- Boot Logic: The system is initiated via bootLoad() and bootStrap() to populate memory and configure modules.

Each component operates in asynchronous or synchronous cycles, coordinated via a central processing loop that maintains logical consistency.

## D. JUMPSETS & OPTIMIZIZATION

To address potential resolution bottlenecks or high-cardinality domains, MSS introduces Jump Sets—pre-computed sets of often-used domain references. These allow address resolution to shortcut through a curated space of frequently meaningful relationships.

Jump Sets are used:

- To reduce computational overhead.
- To cluster related values for faster interpretation.
- As a fallback heuristic when meaning is ambiguous or partial.

## E. ATOMIC DOMAIN CONVENTIONS

At the lowest level of MSS, atomic domains function via rule-based interpretive contracts. Each atomic address pair resolves into a known semantic, symbolic, or numerical value. This contract may be formalized as a function:

```
def resolve_atomic_value(element1, element2):
        return f"{element1} ~ {element2}"
```

All schema logic defers to these resolutions at its base, allowing upper-layer structure to remain modular and interpretable.

## F. EXTENSIBILITY & INTERFACE STRATAGY

The Mycite Framework is designed with extensibility as a primary goal:

- Modular plugins for additional archetypes or schema types.
- Interface abstraction layers (e.g., CLI via Hyphae, visual interface via Bloom).
- Real-time input/output orchestration through asynchronous streams.

These design principles enable future expansions into new media types, automation contexts, or network-based multi-node environments.

## G. TERM DEFFINTIONS

Code - A system that establishes a one-to-one functional relationship between two distinct, finite sets of elements.

- E.g. given the assignment {Y = 4, O = ★, U = #}, then the sequence '4★#' is equivalent to 'YOU'.

Encryption - The process of converting a set of original data elements into a new, related set. This transformation uses mathematical and algorithmic logic, where numerical values from the original data guide a unique conversion process.

First order Elements - The most adjacently visible form of what makes up the sum of what is an instance of information.

- E.g. A visible view of a display screen might be considered an instance that is made up of pixels, made up of the RGB lights that make up those pixels (lessened abstraction), or it may be considered a top level topic of display that is made up of information like text and pictures.

View Value - A value that relates to the size of a space.

Focus Value - A value that relates to the magnitude of deviation of 1 space.

Field-Archetype - A denoted model that represents the value for which an instance can be a representation of a certain type.

- E.g. An instance of which has a View-value of 10,000 and a Focus-Value of 3 can be used to describe an instance of 30,000 first order elements

Babel Address - Denotes the predetermined value of each first order element for an instance of a Field-Archetype class, by having all possible instances of an Field-Archetype (given a first order element) ordered by the exponential operation of change of the first order elements (Bound by its possible values).
