INFORMATION TECHNOLOGY SOCIAL SYSTEMS: THE MYCITE PROJECT, WHAT IS AT RISK, MITIGATING HARM, VALUE PROPOSITION, & WHAT IS BEING DONE

AUTHORED BY: DYLAN MONTGOMERY

ABSTRACT

The Mycite Project is a mission-driven effort to support public awareness of systemic information problems and to develop the Mycite Framework Technology as a solution. This report outlines the need to establish a new foundation for the information technology industry. One that recognizes the impossibility of information ownership, addresses the threats posed by continued adherence to outdated models, and proposes a decentralized, standards-based system for the ethical and resilient use of information.

1. INTRODUCTION

In the modern world, our lives are shaped by systems built around a dangerous misconception: that information can be owned. This fallacy underpins digital economies, surveillance regimes, and power structures that are rapidly becoming incompatible with the reality of technological progress. At the same time, quantum computing, artificial intelligence, and networked digital tools are accelerating the collapse of these systems from within. Societies face a binary illusion: either cling to failing structures until collapse, or tighten control through surveillance and digital authoritarianism. Yet a third option exists. One that demands new assumptions, new governance, and a new digital infrastructure.

The Mycite Project is a response to this moment. It is grounded in the view that our social systems must transition from containment-based models of information control to contribution-based models of interaction. This shift is both moral and practical. Just as energy cannot be owned, only harnessed and directed, so too is information a force of nature; subject to entropy, recombination, and discovery. The question is not whether this transformation is coming, but whether we will meet it with foresight or be overtaken by crisis.

2. BACKGROUND

The study of Surrealmatics [*the philosophical and technical understanding of information as a natural force*] offers a critical lens for interpreting the present. Information exhibits characteristics analogous to physical forces: entropy, momentum, semantic density, and recursive structure. These traits reveal why the traditional model of ownership is not just impractical, but incompatible with the behavior of information itself.

Information, like energy, flows and disperses. Its value is not static, but created through intentional arrangement. As AI systems show, “creation” is merely the recombination of known elements into new arrangements. In a finite digital universe, such as all possible strings of a given character set, novelty is not invention, but discovery. As systems like language models traverse these possibility spaces, they blur the lines between author and algorithm, creator and tool.

At the same time, information is becoming denser and more accessible. Each discovery adds to a collective field of knowledge, accelerating our ability to build on prior work. Like a fractal, new truths emerge from recursive refinement, whether through deep, focused analysis or broad, high-level synthesis. This scaling behavior collapses traditional hierarchies of expertise and ownership, placing greater value on contribution, intentionality, and perspective.

Understanding these dynamics is essential. As with the physical world, ignoring the natural properties of a system does not prevent its consequences, it only increases their severity. The remainder of this report will examine the systems currently built on false premises of information ownership, the dangers they now pose, and the third-way alternative enabled by the Mycite Framework and its application in local, decentralized systems like agriculture.

2.1 INTENTION

The boundary between invention and discovery has eroded. This erosion is not a side effect of artificial intelligence but rather a revelation made clear. It compels us to reconsider what it means to create when all possible arrangements of information already exist in a definable space. A thousand-character page, for instance, composed from a set of 29 characters (letters, space, punctuation), has a finite number of permutations. Though vast, that space is not infinite. It is mappable. In this context, AI does not invent. It navigates.

When we understand content as instances drawn from a larger field of possibilities, originality becomes a matter of intention and selection rather than exclusive creation. The act of choosing, interpreting, and arranging from a field of known components is what we value. Not the false notion that such arrangements can be owned.

The implications extend beyond AI and into all domains where creativity is celebrated and monetized. As machines outperform humans in navigating and rearranging data, our economy must shift from rewarding novelty of output to rewarding novelty of perspective. The artist, the thinker, the builder; they contribute not because their elements are new, but because their arrangement says something real.

In the end, intentionality is what grants meaning to arrangement. It is the force that transforms permutation into expression. Our systems must be redesigned to value and protect intention, not to imprison expression in cages of artificial ownership.

2.2 ENTROPY

Entropy is the foundational principle that explains why information cannot be contained. It is a natural law of information that governs digital systems. Like energy in traditional physics tends to move from a confined system, information tends toward proliferation. Information can not sustainably exist at the same time be kept from escaping any isolation. Attempts to resist this behavior through secrecy, encryption, or restriction are ultimately temporary, brittle, and destined to prolong the inevitable.

Today, digital infrastructure relies on encryption to enforce boundaries. Simply put, it allows points of contact to identify themselves across public lines of communication to establish a connection that is highly obfuscated. In essence, mathematical protocols are relied on to assume that a party is who they say they are and they are the only ones to be able to read information sent. These protocols work not by stopping information from spreading, but by obscuring it in such a way that only the right recipient can decipher it. Yet this fragile control mechanism faces extinction in the era of quantum computing. Despite the proposition of possible encryption methods that could solve shortcomings, in short, quantum computers will be capable of breaking the very foundations of our current encryption model.

There are already massive operations by capturing and storing encrypted data, with the assumption that in the near future it will all be easily deciphered.

Recently, its been observed, the leaps forward in sensory interfacing. By examining the pattern in across different images being shown to a subject and how they align or differ based on the images stimulation in the brain; scientist have shown proof of concept in an ability to make sense of the current attention of a subject's brain, with out ever having to know the complexities of how it works.

Furthermore, in recent years we have seen the unmanageable task of enforcing piracy laws. It is understood that if information is being transmitted to a personal device, that it can be captured. In response, large tech companies have employed restrictions on the devices that we use, under the guise that we do not own the software that operates them. Making it illegal to reverse engineer, what is in essence, a pattern of electrons that makes our devices work. As this pattern continues we will see centralization continue to be favoured as it is no leap in logic that we wish to have an economic system that rewards people's new ideas and effort to bring them about. However the flaw in this, is that it assumes that there is no other way to achieve this ideal.

This is not a purely technical problem, it is social, legal, and ethical. Systems today outsource liability for breaches to individuals, expecting users to defend themselves within infrastructures they cannot inspect or control. From massive data leaks to the criminalization of reverse engineering, our systems blame the user while protecting the opaque logic of closed software and proprietary design.

But entropy cannot be negotiated with. It is only by aligning with its inevitability that we can build resilient systems. This means shifting from an ethos of containment to one of coordination. Instead of locking data away, we must design systems that embrace openness, auditability, and decentralization, not as idealism, but as realism. The true protection of data in an entropic world lies not in stronger locks, but in better structures of shared stewardship.

2.3 EMBODIMENT

Information is not simply an external resource, it is a living force that evolves through interaction. Like a fractal, information exhibits recursive depth: zooming in reveals new structures, while zooming out reveals larger patterns made from the same essential elements. This means that discovery is not just a function of scale or novelty, but of perspective and arrangement. The same energy, applied with focus or breadth, can yield insight, depending on the structure of what's observed.

As technologies increase our capacity to perceive, interpret, and manipulate information, we must recognize that all new knowledge is fundamentally a rearrangement of what is already known. This is not a limitation, but a powerful principle. Just as atoms are reused endlessly in nature, ideas recombine endlessly in culture. The process of knowledge creation is an act of recombinative embodiment; transforming existing informational components into meaningful new constructs.

This realization has profound implications. It means that intelligence, whether artificial or human, is not a source of spontaneous originality but a filter of meaningful rearrangement. The value of a contribution is measured not by its raw materials but by the intentional synthesis of structure and context. As information becomes denser, the opportunity space for meaningful discovery grows. Not linearly, but exponentially.

Yet our systems still attempt to define ownership over these rearrangements, denying others the right to interpret or reuse what has been structured. This is the embodiment of a false scarcity. A refusal to acknowledge that meaning emerges not from exclusivity but from accessibility.

The Mycite Project views embodiment as the living intersection between individual intention and the shared informational substrate of the world. It is this interface; between the internal and the external, the focused and the expansive; that must be supported by future systems. When we support individuals not by gating access, but by enabling expression and interpretation, we align our tools with the nature of information itself.

3. PROBLEM

The systems we have built around digital information are collapsing under the weight of their contradictions. At their core, these systems are structured on the illusion that information can be contained, owned, or permanently restricted. Instead of adapting to the true nature of information, they rely on increasingly brittle controls; encryption, legal silencing, and centralized access; that are quickly becoming unsustainable.

This failure is not technical alone, it is philosophical. Attempts to monetize information through ownership presume a kind of scarcity that information does not possess. Unlike finite goods, information spreads and multiplies upon contact. When economic models treat it

as a commodity to be hoarded, the result is not only inefficiency, but harm. Closed platforms, proprietary formats, and user surveillance are not side effects. They are necessary consequences of a system trying to contain the uncontainable.

What we face now is not just systemic risk, but moral decay. The burden of security is placed on individuals who are neither equipped nor empowered to defend themselves. Users are blamed for breaches, fined for circumvention, and penalized for seeking transparency. All while corporations consolidate control, obfuscate accountability, and privatize access to knowledge. This imbalance is unsustainable and unethical.

Without acknowledging the impossibility of owning information, every attempt to govern digital space becomes a performance of control rather than a practice of care. Law becomes weaponized, trust becomes transactional, and innovation becomes exploitative. The more we enforce ownership, the more fragile our institutions become.

The Mycite Project stands in direct opposition to this trajectory. It calls for a fundamental declaration: information cannot be owned. This is not a rejection of privacy, authorship, or credit, but a rejection of structural hoarding and digital feudalism. From this declaration follows a necessary redesign: one that treats information systems as stewards of flow and contribution, not gatekeepers of value. The remainder of this report explores how such systems can be designed, governed, and sustained.

3.1 ECONOMICS

Value in a digital society cannot be priced as if it were grain or gold. Classical economics linked price to scarcity: land, labour, raw material. Scarcity economics breaks down for information, by contrast, as digital artefacts are infinitely replicable. Licensing, DRM and patent fences merely simulate scarcity as a distortion of what is reality. This model was fine for a time, as we wish to reward those that contribute, but as this underlying idea erodes, so do many other institutional operations.

Information breaks the four-goods box. Public, private, club and common goods are defined by rivalry and excludability. Information is naturally non-rival (my use leaves yours intact) and non-excludable unless we add artificial gates. It behaves more like a semantic commons: value is created when people arrange, interpret and recombine shared meaning.

Misaligned Incentives of “Ownership” are rising to the surface of public discourse in conversation about the student-debt model. Tuition is priced as though universities could repossess knowledge if payment lapses. Once learned, however, knowledge lives with the student. Like eyeglasses that permanently sharpen vision after purchase. The result is economic drag: lenders extract rents from a resource that no longer exists as a scarce asset. These Lock-in models try to reclaim perpetual value from knowledge that cannot be repossessed, leading to economic and moral inefficiency.

Automation amplifies this distortion. If proprietary AI platforms lease the “software brains” that run factory robots, one vendor can steer an entire national workforce and govern an entire labor market even when citizens “own” the hardware. Safety regulation for self-driving cars and drones makes this monopoly path politically tempting unless open standards intervene.

Orchestration, not ownership, creates Impact. Economic value in the information age arises from time, insight, raw materials and energy, not from hoarding bit-patterns. Mycite proposes a contribution-first accounting layer that measures who arranged what, when, and for whom, rewarding orchestration over exclusion. It lends itself to only an empirical defense of information being structured so that there is no question of what it is and how it exists. This does not prevent identity, merely leaves as the sole responsibility for those that wish to govern a system of trust, with no control over the free flow of information. A live prototype of how this might work is seen in Barcelona’s Fab-City. The city’s “locally productive, globally connected” programme routes digital design files through open Fab Labs while sourcing material nearby. The payoff: reduced waste of material, reduced waste in energy, resilient supply chains and community-level innovation. It proves that open design + local fabrication can out-compete linear, ownership-centric supply chains.

Transition is inevitable. Failing to adapt courts systemic risk. If society clings to information ownership while local fabrication and AI march on, we’ll be blindsided by power concentration and missed ecological/innovation gains. Local manufacturing and ubiquitous AI are coming, with or without new rules. Clinging to proprietary control will centralise power, stifle participation and leave societies unprepared for a world where anyone can fabricate almost anything. Embracing a contribution economy now (through frameworks like Mycite) lets us capture the upside while distributing agency.

Scarcity logic made sense for grain and gold. In an era of recombinant code and local fabrication, prosperity flows to systems that coordinate contribution rather than gatekeeper copies; but information doesn’t fit the four standard goods classes as it is naturally non-rivalrous and non-excludable. I behave more like a shared semantic commons than a private, club, public, or common good.

3.2 TRUST

Trust is the substrate of any society. When the flow of information becomes the basis for identity, coordination, and agency, trust is no longer a social courtesy. It is infrastructure. But today's systems have built that infrastructure on a paradox: they ask users to trust systems they cannot see, while holding them accountable for outcomes they cannot control. If those channels are opaque, society’s foundation rests on blind faith. Certifications, marketing, and compliance badges simulate assurance; without verifiability they amount to coercion.

The opacity paradox has established modern devices to ship to consumers with closed-source software, proprietary firmware, and black-box algorithms. Users must “agree” to unseen code, yet are those that are burdened when systems fail. Users are seen as individuals who knowingly risk their data’s privacy, simultaneously, these applications and devices are privately owned, and are not responsible for any level of tailored function despite or open to audit. Meanwhile people are left without alternative options to compete in today's world and choose to be responsible to keep their information from risk. When that code leaks passwords, deepfakes their likeness, or locks a bank account its seen security is promised but unverifiable.

- Data-breach settlements compensate for companies' reputational loss; victims still repair credit for years.
- Reverse-engineering to audit risks is criminalised, insulating vendors from scrutiny.
- Alternate apps are disabled or declared “insecure,” leaving no functional exit.

Liability is deliberately misallocated. Corporations harvest data and externalise risk (breaches, fraud) while outlawing scrutiny and blocking alternatives. When they do suffer consequences it is seen as a payment to do business, not as a punishment. Corporations monetise personal data while externalising fallout. From phishing to identity fraud, users absorb the damage, courts accept digital logs as character evidence, and social-security numbers remain the brittle master key. In practice, we “own” devices in name only. What this puts on display is a system that is not called into question on the basis that it collects our information, it calls into question a complete lack of choice to avoid risks. It will continue to be more difficult to prevent the spread of our data, and so the flaw is that this is capable of being a risk.

As a society continues to avoid rethinking its ownership of information, in place of new systems, companies will continue to rise to the task of confirming a person's identity and what is true and what is not. A people’s only option being the use of those same companies for live verification codes to enable our access to invaluable digital resources, even our banks, health records, and taxes. Opaque control endangers democratic self-determination. When a handful of vendors or agencies arbitrate “who you are” and “what is true,” civic power shifts from people to gatekeepers. This is unavoidable, in the form of companies or governments. It merely poses the question how we might decentralise this identity and system of trust. Verifiable, distributed trust demands open, local, interoperable tools. Mycite proposes such tools, treating information as unownable and pushing custody/inspection to the edge rather than the centre.

3.3 TUST-LESS

Systems built on “ownership of information” will break, not bend. The assumption of information ownership has driven the design of both legacy institutions and emerging technologies, but neither can escape the consequences of building on a false foundation. Whether enforced through legal mechanisms, cryptographic walls, or proprietary ecosystems, the result is the same: fragility, centralization, and eventual collapse.

Consider Bitcoin’s proof-of-work ledger. It was designed as a decentralized alternative to institutional finance; a ‘trustless’ collaborative network. Claims of certainty assert that ownership does not need to be trusted or not trusted, it can just be certain. Currency outside state control. But by embedding its use in decentralization and proof-of-work mechanisms, it enshrines informational rigidity. It is a known fact that crypto-currencies, without having a central authority to update its manner of encryption, will inevitably fail. This is the case even without quantum computing on the rise. Bitcoin exposes the paradox of trying to decentralize while still clinging to ownership logic: the ledger is open, but control is rooted in accumulation and exclusivity and like all systems based on encryption, without a central authority to update its operations, it will fail. Not to mention its spiraling energy consumption, risk of a 51% attack and volatility.

Ethereum, in contrast, has avoided collapse by pivoting toward centralized coordination. Despite being marketed as a decentralized platform, Ethereum depends on core teams, curated updates, and emergent hierarchies to maintain momentum. Its resilience is not proof of decentralization, but of the implicit re-centralization needed to stabilize systems that attempt to own programmable logic. It has become just another privatized fiat-currency, like flight reward points. Not that there isn't value in either but rather they don’t represent what people think.

True decentralization within a trustless network hinges on prioritizing information credit rather than ownership proof. Consequently, blockchain becomes truly advantageous when employed by localized democratic communities to validate credited information. This approach maximizes blockchain functionality and ensures sustained use, but requires a small trusted group for centralized control. Paradoxically, attempting to decentralize information ownership without centralizing control results in either unsustainable outcomes or a false sense of autonomy. These insights reveal the limitations of models that overlook this fundamental relationship. Furthermore, this framework can be scaled to represent a state ledger aggregating county contributions into a national ledger. Similarly, private sector companies, churches, schools, or the creation of an inheritance-based digital research database can benefit from this model.

This may end up with national connected networks typically aggregating trust ledgers from immediate levels below, like states collecting data from counties or cities. While an internet without strict identity control is possible, there's a demand for a unified communication system founded on individual connections. This structure would restore journalism's utility, as news becomes meaningless without it. Implementing this is challenging, so the Mycite Project aims for a hyper-extensible system, based on technically enforceable and socially distributed trust. That means building tools that are:

- **Open by default, so behavior can be inspected and improved by anyone.**
- **Interoperable by design, so no single vendor can monopolize access.**
- **Locals in custody, so individuals retain sovereignty over the data they use to inform decisions at the very least.**
- **Semanticly designed so that the framework never falls out of date, only the implementation.**
- **Allow for central authorities to be broken up into layers for needed updates and changes.**

Instead of striving for a trustless Web 3.0, like earlier efforts, the Mycite system focuses on information as it exists, without prioritizing ownership. This approach achieves genuine trustlessness: information is definitively what it is underwood to represent. Actions of navigating, mediating, referencing, and manipulating information are not put at risk of mismanagement only vulnerable to falsity that a person chooses to push. Even then for application such a research, references can inherit true references that don’t have the ability to represent anything but what they represent.

3.4 TECHNOLOGY & POWER

Technology is not neutral, it is an amplifier. It does not create power, but redistributes and concentrates it. Every technological shift in human history has changed who holds power, how it's exercised, and what forms of governance can persist. And each time, those unwilling to adapt have been swept away.

The agricultural revolution allowed a few to feed many, enabling cities, states, and kings. The printing press shattered the monopoly on scripture and sparked the Reformation. The internet replaced gatekeepers with hyperlinks. And now, artificial intelligence, cryptography, and quantum computing are collapsing the remaining boundaries around knowledge and coordination.

Each of these waves increased the total power available to society. power to act, to know, to influence. But this growth is not linear, and neither are its social consequences. When the distribution of power diverges too far from the systems designed to manage it, a tipping point is reached. Systems centralize, resist, or collapse.

Historically, the beneficiaries of each wave built new institutions to preserve their advantage. Universities rose after literacy spread. Broadcast empires ruled the airwaves. Today, tech monopolies govern our data and devices. But the cycle always turns. Individuals can now create what once required teams; organize without hierarchies; build systems without permission.

This shift demands a new model of coordination. One that does not attempt to reclaim control through digital empires, but distributes capability through digital commons. Mycite sees this not as a challenge to governance, but a call to redesign it. The tools of today allow for coordination at scale without centralization. If the systems we build are aligned with the properties of the tools themselves.

Technology’s momentum cannot be paused. But it can be steered. And whether that momentum leads to collapse, coercion, or collective stewardship depends entirely on whether we embrace the redistribution it demands.

3.6 CRITICAL POINTS

History doesn't just repeat, it compounds. Each new tool, system, or idea adds to the cumulative complexity of society. Over time, these layers reach a breaking point, where the assumptions that once held society together begin to tear it apart. We are living through one of those critical transitions now.

From education to economics, from governance to media, institutions built for a world of scarce information are straining under its abundance. Systems that once relied on centralized control, secrecy, and hierarchy are colliding with a public that can search, synthesize, and self-organize in real time. As a result, the gatekeepers are doubling down, fortifying walls, tightening laws, hoarding access.

But the pressure cannot be contained indefinitely. The more power becomes concentrated without consent, the greater the risk of collapse or authoritarian control. These are not conspiracy theories; they are historically recurring outcomes when institutions attempt to preserve power through force rather than reform.

The transition we face is not optional, it is structural. Either we distribute power with intention, or it redistributes itself through upheaval. The good news is that we now have tools to make that transition peaceful and productive. We can design systems that scale cooperation without centralization. But doing so requires rejecting the mental model of ownership, and the institutional reflexes that come with it.

The Mycite Project identifies this inflection point not just as a risk, but as a chance. A rare historical window in which a better system can be built, not imposed, but adopted. Not enforced, but trusted. Not sold, but shared.

This is not a call for revolution, but for renovation. The walls are already cracking. We simply propose building exits before they fall.

4. SOLUTION

The collapse of ownership-based information structures isn't merely a technical inconvenience; it's a coordination failure that threatens social cohesion, economic stability, and informational trust. The Mycite Framework was developed to offer not just a technical patch, but a reimagined way of engaging with data that respects entropy, context, and autonomy.

4.1 THE CONTROL GATE DESIGN

At the heart of Mycite is the Control Gate. A system design framework that operates less like a program and more like a decision-making process. It does not control information, but mediates between attention, intention, and context. By reflecting the user's focus, goals, and semantic orientation in real time, it allows digital systems to act more like collaborative tools than command hierarchies.

The Control Gate simulates the layered nature of human decision-making by prioritizing context over commands. Events are parsed into four categories: Navigation, Investigation, Manipulation, and Mediation. Then those events are dispatched to update system state based on their context and significance. Asynchronous signals are harmonized through a single cognitive loop that preserves meaning while adapting to change.

4.2 THE MYCELIUM SCHMEA STANDARDIZATION

The Mycelium Schema Standardization (MSS) is a new ontology of data that supports the Control Gate. This is a semantic address-space model where information is never “fixed” but always contextualized. Here, tables define domains, and domains define how to interpret references. Meaning is deferred through layers until resolved at an atomic domain via shared conventions.

This destroys the foundation for centralized ownership: value is no longer attached to files or instances but to interpretive paths. MSS is more than schema; it’s a living ontology for information, inherently structured for interoperability, decentralization, and clarity.

4.3 THE MYCITE FRAMEWORK

Local Use Case: The Framework as a Tool for Individuals or Organizations; the Mycite Framework can serve individuals or institutions seeking to manage dynamic data with high fidelity and ethical integrity. Within a design studio, for instance, Mycite can map creative focus, track process outcomes, and ensure consistent semantic feedback between clients, projects, and production tools. All without surrendering control to a third-party platform.

Every directive becomes a piece of context-rich intent, not a locked-down transaction. Data navigation becomes a dialogue rather than a command prompt. This enables greater modularity, auditability, and adaptability.

4.4 THE MYCELIUM NETWORK

Scaling to Networks: The Mycelium Network and Decentralized Interoperation. Beyond the single-user model, the Mycelium Network allows these systems to interoperate without resorting to central servers. Each node maintains its own schema instance, and interactions occur via agreed-upon domain resolutions. There is no central hub, only shared mappings.

Trust emerges not from encryption alone, but from visibility into context chains, resolution paths, and transformation flows. Just as language requires mutual understanding, Mycite frameworks synchronize not by force but by interpretive alignment.

4.5 THE IMPLEMENTATION ENTRY POINT

Agriculture is the ideal proving ground: it combines high-entropy coordination problems with low digital agency. Farmers manage complex systems of input, timing, and biological response, yet are often locked out of their own data by proprietary SaaS tools.

Mycite empowers farmers to:

- Define and manage their own schema of operation.
- Share insights across co-ops or regional networks without risking central lock-in.
- Contract engineering support (e.g., via Fruitful Network Development) on a modular, competitive basis—building an ecosystem where tools serve people, not platforms.

4.6 THE MISSION ROAD MAP

To navigate deployment, support, and growth; the Mycite Project's ongoing mission intends to:

- Deploy early-stage implementations with farming collectives.
- Develop and share free, modular toolkits built atop Control Gate and MSS.
- Serve as a public steward of these standards, not a gatekeeper, but a model of sustainable alignment.

The long-term goal is to establish a cooperative software industry that scales the values of trust, clarity, and interpretability. Mycite is a blueprint for how we can move past the illusion of ownership and into an era of contributive digital agency.

5. CONCLUSION

[Discussion Here; about how this and why this reality calls for a new path forward and why the solution provided is the best path. Also discusses how the Mycite project aims to develop awareness of these issues, and after developing the industry the mission driven effort aims to create an s-corp artificial intelligence company that serves to propagate a collective consciousness, rather than an owned product. Perhaps also discussing effort to establish state level agencies to help integrate digital rights and services]

APPENDIX

A. THE CONTROL GATE SYSTEM DESIGN

The Control Gate is the Mycite Framework's core control loop, acting as the synchronous center of a modular, intention-based program. It integrates user and system inputs by classifying them into four primary intent types: Navigation, Investigation, Manipulation, and Mediation. These are then dispatched through an interpreter to update the AppState, which represents the live contextual model of the system's current focus, visible structures, and linked meanings.

This architecture allows for:

- Real-time updates to system state from asynchronous inputs.
- Intent classification that preserves semantic relevance.
- Reflection of decision-making logic directly in application behavior.

By mirroring cognitive attention systems and filtering updates based on contextual thresholds, Control Gate enables systems that feel cooperative rather than deterministic.

B. THE MYCELIUM SCHMA STANDARDIZATION

MSS defines a hierarchical, recursive schema system where each instance (or record) is interpreted through the lens of its domain. Domains themselves are tables, and values resolve downward toward an atomic domain—where interpretations follow conventional or symbolic meaning rules.

Key features include:

- Schema instances modeled as object-oriented entities.
- Address resolution through domain layering.
- Deferred meaning via semantic networks and interpreted relational paths.

This creates a stack of nested contexts, akin to a semantic address space. Meaning emerges not from static content, but from the resolved relationships of structure and context. MSS is thus a symbolic runtime for data meaning.

C. DATA HANDLING ARCHITECTURE

- Peripheral Modules: StateReadIn, StateReadOut, MyciteReadIn, MyciteReadOut allow for modular integration of user, device, and network I/O.
- AppState: Maintains the live state of attention, view, earshot, and queued intentions.
- Boot Logic: The system is initiated via bootLoad() and bootStrap() to populate memory and configure modules.

Each component operates in asynchronous or synchronous cycles, coordinated via a central processing loop that maintains logical consistency.

D. JUMPSETS & OPTIMIZIZATION

To address potential resolution bottlenecks or high-cardinality domains, MSS introduces Jump Sets—pre-computed sets of often-used domain references. These allow address resolution to shortcut through a curated space of frequently meaningful relationships.

Jump Sets are used:

- To reduce computational overhead.
- To cluster related values for faster interpretation.
- As a fallback heuristic when meaning is ambiguous or partial.

E. ATOMIC DOMAIN CONVENTIONS

At the lowest level of MSS, atomic domains function via rule-based interpretive contracts. Each atomic address pair resolves into a known semantic, symbolic, or numerical value. This contract may be formalized as a function:

```
def resolve_atomic_value(element1, element2):
    return f"{element1} ~ {element2}"
```

All schema logic defers to these resolutions at its base, allowing upper-layer structure to remain modular and interpretable.

F. EXTENSIBILITY & INTERFACE STRATAGY

The Mycite Framework is designed with extensibility as a primary goal:

- Modular plugins for additional archetypes or schema types.
- Interface abstraction layers (e.g., CLI via Hyphae, visual interface via Bloom).
- Real-time input/output orchestration through asynchronous streams.

These design principles enable future expansions into new media types, automation contexts, or network-based multi-node environments.

G. TERM DEFFINTIONS

Code - A system that establishes a one-to-one functional relationship between two distinct, finite sets of elements.

- E.g. given the assignment {Y = 4, O = ★, U = #}, then the sequence '4★#' is equivalent to 'YOU'.

Encryption - The process of converting a set of original data elements into a new, related set. This transformation uses mathematical and algorithmic logic, where numerical values from the original data guide a unique conversion process.

First order Elements - The most adjacently visible form of what makes up the sum of what is an instance of information.

- E.g. A visible view of a display screen might be considered an instance that is made up of pixels, made up of the RGB lights that make up those pixels (lessened abstraction), or it may be considered a top level topic of display that is made up of information like text and pictures.

View Value - A value that relates to the size of a space.

Focus Value - A value that relates to the magnitude of deviation of 1 space.

Field-Archetype - A denoted model that represents the value for which an instance can be a representation of a certain type.

- E.g. An instance of which has a View-value of 10,000 and a Focus-Value of 3 can be used to describe an instance of 30,000 first order elements

Babel Address - Denotes the predetermined value of each first order element for an instance of a Field-Archetype class, by having all possible instances of an Field-Archetype (given a first order element) ordered by the exponential operation of change of the first order elements (Bound by its possible values).
