Why the World Needs the Mycite Technology & Why it Starts With Local Agriculture

By: Dylan Montgomery

[Nature of Information]

Surrealmatics is the study of information as a force of nature. The study explores the fundamental attributes of information; entropy, momentum, organization, and semantics; to better understand current events and anticipate uncertain outcomes. While surrealmatics is not a new concept, the rise of AI, quantum computing, and increasing globalization necessitates a shared vocabulary to comprehend the evolving landscape and facilitate clear communication for collaborative problem-solving regarding foreseeable challenges. In the following section, it will be made clear the core falsity of information ownership. However, note that this does not mean that it is also folly to create laws and social contracts that positively reinforce restraint from amoral means of obtaining information, and rather it is only possible to do so if a clear declaration is made that asserts there is no such thing as ownership of information.

[Nature of Information: Intentionality]

- Discovery and Invention

Some assert that many developments in history were inevitable and that specifics are what make them historical. One of these inevitabilities might be the abolishment of slavery. It took the people of this area to recognize the flawed nature of the practice in order to grow a movement that recognized and assert that there was no way forward into the future without expelling this philosophically-amoral foundation out from underneath society. This parallel exists in the argument against ownership of information, without the painfully obvious moral outrage. However the philosophical nature remains.

The concept of information ownership is inherently flawed, a notion that has persisted largely due to the historically slow growth of information and the challenges associated with its access and navigation. However, as information expands exponentially and access becomes increasingly seamless in the coming years, the futility of claiming ownership over information will become undeniable. Such attempts to control information flow are contrary to the natural order and are, in essence, an increasingly unsustainable endeavor.

As artificial intelligence blurs the distinction between creation and discovery by simulating static values within fixed frameworks, the concept of intellectual property warrants re-evaluation. This can be illustrated by a one-thousand character book page. If we assume that each of those characters can be one of the 26 letters of the alphabet, a space, a comma, or a period; then we can say that this book page is one possible instance of all possible versions that can be created. We know exactly how many versions of this book page exist based on its structure, since for each of the one-thousand spaces we can multiply by the 29 elements that might exist there. Albeit it is a very large number, it is finite (1.11247797979979 E14426). Now if we just alphabetize this, it starts to become easy to understand how one might consider any article of content as a long, ordered, list of all possible instances of some page, or picture, or song. This list contains every possible sentence or phrase a human will ever say or has said, every song, every piture. This frames the idea of creation as something that is not new, but rather something that already exists and is waiting to be discovered. This is meant to put in simple terms how we can think about AI and neural networks. As they are trained on finding patterns to navigate these lists of possibilities to discover desired locations. As AI evolves to process diverse inputs like sounds, images, and matter, it will generate invaluable music, movies, and materials. This raises questions about the basis of our claims to ownership, which seem to rest on possession or authoritative decree. Furthermore, our reliance on digital platforms and the trust we place in them, both as users and authorities, adds another layer of complexity to the

[Nature of Information: Entropy]

Information, like energy, operates under the laws of entropy, making it susceptible to spreading or in its absorption e.g. observation. Similar to a physical letter, digital information can be intercepted, read, altered, redirected, falsely attributed to a different sender, or returned to an unintended receiver. Current technological advancements even aim to visualize brain imagery. Potentially making it so that our brain's output of information doesn't only consist of our choice to communicate or to

take outward actions. This all aligns with the concept that information operates under fundamental principles of influence, allowing us to create systems that either align with or oppose these principles. Just as we construct buildings to comply with gravity, internet infrastructures that disregard these information laws are inherently prone to failure. This concept is central to the distinction between asymmetric and symmetric encryption.

Just as is the nature of a letter being sent through the postal system, encryption is just a means of obfuscating falsification. This inherent property is where the potentially exploitable nature exists. The conventional response has been an ongoing effort to develop more complex encryption methods. However, the imminent arrival of practical quantum computing, renders this approach increasingly vulnerable. Quantum computers can calculate probabilities rather than definitive answers, demanding significantly less computational power and resources. The key take away is that this paradigm shift necessitates a fundamental reevaluation of our current global societal framework. There is not a clear future without the ability to confirm someone is who they say they are over the internet.

[Nature of Information: Embodyment]

Our inherent desire for truth is clear, and we often perceive the unexpected discovery of it in various forms as beauty. We actively seek these truths across all levels of complexity, within diverse values and aspects of our lives and existence. This satisfaction even extends to exploring unfamiliar territories and realizing they hold more significance than our initial understanding.

If we consider technology as analogous to mass and power to gravity, their historical interplay reveals a mutual growth. Information, in contrast, has always been a counterforce to the physical. Evolution, with its inherent drive, also operates outside these purely physical laws. The laws of thermodynamics define limitations overcome by information and the potential of ideas, leading us to surrealmatics, the study of information's nature. Throughout history, technological advancements appear as discoveries of order, where existing knowledge is recombined to create novel entities. These creations act as inherited knowledge and as catalysts for further innovation, resulting in something greater than the individual components. This process is a cyclical interplay of intent and discovery, generating power – the capacity to achieve more.

As these discoveries unfold and global power increases, the connection between power and structure becomes evident. The rise of agriculture, specialized labor, and government necessitated organized power within hierarchical structures. This facilitated the execution of intentions and, in turn, contributed to the cycle of power generation. However, history reveals a pattern: these power structures periodically reinvent themselves. When the total power exceeds the capacity of the existing social order, this surplus power becomes accessible to the general populace. This ultimately necessitates the adaptation or creation of new governmental or social organizations, evolving from tribes to communities to territories to monarchies to republics, driven by advancements from the alphabet to the internet. While these social structures are essential, they risk obsolescence if they fail to adapt swiftly to an increasingly informed, connected, and capable citizenry.

[Principled Design]

- How the current society will predictably collapse
- What kinds of systems reinforce or resist that reality

Consider the argument that it makes for why the entropy of information will continue to expand and how this points to an inevitable erosion of any system of society that depends on owning information, by effect of asymmetric encryption dependency. Then examine how it aims to connect this idea to the Consider the merit in the writing's choice to explain the fundamental nature of symmetric and asymmetric encryption, and how the reader can simply understand quantum computing's nature that will eliminate the current use of asymmetric encryption. Consider how it uses this established reality of future events to lay out how social systems have been built to completely rely on the encryption of information while putting the burden of responsibility of protecting one’s own information on the individual and also baring them from any feasible means of doing so. This is meant to lay out for the individual the flaw in these systems is that there is no ability for an alternative, as long as these systems stay a centralized, proprietary domain, so there are other options but it would require and centralized digital governance to merely be one that standardizes information representation, but leaves any responsibility of being the sole

handler, in the past. The writing then applies these ideas to data leaks and their responsibility imbalance, how this applies to proprietary software and a lack of interoperability to interact with alternatives.

Finally, how might this subsection's content be revised to better communicate its aimed flow of argument with its contents, via the connecting of ideas and explanation of complicated subjects to support an informative argument that follows the intended flow and supported arguments.

[Principled Design: Economics]

In economics, goods are categorized into types by two fundamental features that distinguish these types: excludability, which determines if consumption can be limited, and rivalry, which indicates if one person's usage hinders another's. The four categories being: private (excludable, rivalrous), public (non-excludable, non-rivalrous), club (excludable, non-rivalrous), and common resources (non-excludable, rivalrous).

In our current system we have large swaths of industry that are predicated on definitions of what might fall into these groups. In most cases, it only makes sense to have a system to reward those that do the work to produce something new, and this doesn't happen to be the fundamental flaw. The lack of stability comes in the form of the practicing continued benefit, as if the new thing continues to be new, even after being known. Thus, there are adjustments to a new approach for some industries like streaming services. Thankfully in their case, they already have an accurate name. The continued service that they provide is the service of storing information of a certain type, that allows their patrons to access when and where they so choose. The adjustment would likely be mostly focussed on their shift to prevent and enforce their dueled ownership of this content. This would likely make many free digital storage as economically unsustainably, as its value grows and other streams of revenue decrease.

To illustrate this force of adjustment and possible solutions, we can consider the proliferation of AI, capable of analyzing and rearranging finite digital elements. This suggests a significant upcoming change in the concept of ownership for digitized creations. While individuals now possess the means to independently produce high-quality content like movies, music, digital art, and videos, this widespread accessibility diminishes the value of individual works when compared to studio productions and the sheer volume of available content.

Consequently, the focus shifts from the polished novelty of the creation itself to the unique perspective and message of the artist. In this environment, art gains value not from being merely new, but from embodying an original thought, representing a genuine part of an artist's ongoing journey and documented in their chosen medium. This documentation becomes the desired commodity.

However, a challenge arises in how artists can monetize their work when it risks being fed back into AI, generating algorithmic outputs beyond their control. The solution lies in offering truly novel creations. The traditional model of profiting from being the first to discover an idea or copyrighting a specific arrangement of existing elements to control its use is becoming obsolete.

[Principled Design: Trust]

- How systems of trust disappear: supporting evidence, identity, journalism, etc.
- Revise to put systems of trust at the forefront and the determination of encryption based systems as support

In today's society, data remains "owned" largely because of asymmetric encryption—specifically, the pairing of public and private keys. This encryption model enables strangers to securely exchange secrets over the internet and is fundamental to banking systems, digital identities, software licensing, and the secure communication protocols we rely on daily. Without this encryption, verifying digital identities, ensuring transaction authenticity, or protecting sensitive personal information would become infeasible.

However, this foundation is critically threatened by quantum computing. Unlike traditional computers that tackle encryption through labor-intensive computations, quantum computers leverage principles of quantum mechanics to rapidly compute probabilities, drastically shortening the time and effort required to break current encryption methods. This means quantum technology will inevitably undermine asymmetric encryption, posing an existential threat to digital security

infrastructure as we currently know it.

At the heart of this vulnerability lies entropy—the fundamental principle that information tends toward dispersion and exposure. As entropy naturally expands, centralized organizations become increasingly incapable of safeguarding the data entrusted to them. Data breaches routinely expose personal information, yet the consequences disproportionately affect individuals, not corporations. While companies may comfortably absorb fines, affected users bear the brunt of identity theft, compromised credit ratings, financial insecurity, and even professional consequences if employers hold them accountable for these security failures. This lopsided accountability model forces individuals into a precarious position, entrusting their most sensitive data to opaque systems that cannot be independently verified or securely managed.

This opacity is primarily a result of closed-source software and proprietary firmware, which lock users out of understanding precisely what data is collected, how it is handled,

In today’s world, an individual has no choice but to use technology in their daily lives, if they wish to stay in pace with everyone else. However, the development of the infrastructure that makes these tools possible were born out of a world in which people owned information. Thus as we look at how this infrastructure and these institutions measure up to a coming age of quantum

Data leaks are a clear and present danger for risk companies, exposing user data collected for profiling and service delivery. However, the consequences differ drastically. While companies face fines or class-action lawsuits they can often absorb, affected users face identity theft, potentially leading to safety risks and damaged credit scores, hindering their ability to secure essential assets like property. Despite these risks, users often lack alternatives if these data-handling companies are integral to their daily personal or professional interactions. Adding to this precarious situation, employers might hold individuals accountable for impersonation resulting from leaked personal data, implying irresponsibility on the user's part.

The closed-source nature of these companies' software exacerbates the issue. Individuals cannot scrutinize the programs operating on their devices to understand what data is being recorded and transmitted. Even if a user were to undertake the complex task of reverse-engineering the software or hardware, they are legally barred from sharing their findings. This highlights a core problem: the concept of information ownership. Companies and individuals often treat information as a marketable commodity, attempting to control its distribution as if it were a tangible product. However, unlike a club membership with a physical space, information lacks such boundaries. Once a secret is shared for payment, the recipient, unless bound by a non-disclosure agreement, isn't obligated to keep it, especially if safety is at stake.

Information providers should not expect perpetual profit or ownership of information once it has been accessed and potentially disseminated. While storage services for information are understandable, preventing individuals who have paid for this service from retaining and using their data as they see fit is increasingly unsustainable. Value must be earned through added benefit. This principle also applies to the pharmaceutical industry and the notion of drug "ownership." As AI advances and improves in identifying patterns for creating new drugs and information—or rather, discovering novel combinations of existing knowledge—the question of ownership in such contexts requires careful consideration.

The ongoing debate of choosing between a dealership and an independent mechanic reflects a fundamental trade-off: standardized quality and higher cost versus potentially lower cost but uncertain quality from individual operators. While most prefer an honest local mechanic, unfamiliar circumstances often lead to the safer option. This dilemma, present in our automotive choices, highlights our societal structure's acceptance of individual preference.

However, this freedom of choice is absent in our interaction with digital devices. Unlike cars, our web-accessing devices offer limited options. Their integrated architecture, proprietary firmware, and closed-source software restrict user control. Moreover, these partially owned products rely on fragile foundations, necessitating a vast cybersecurity industry for protection. Our financial well-being, tied to these systems and sensitive data like social security numbers, further underscores our vulnerability. Even employers may hold us liable for data breaches originating from our compromised devices.

Despite the advantages of current systems for those seeking convenience or trusting established expertise, a genuine alternative is needed. Individuals should have the option to truly own their purchased technology and manage their risk

exposure. This necessitates a different approach, one centered on user-controlled hardware and software solutions.

[Principled Design: Difficult Acknowledgement]

Why we can't expect to be private, but we can expect even playing fields.

What a declaration of independence from ownership of information and a transition to laws and social contracts that uphold negation of amoral means of obtaining information, and not the 'theft'.

Now it is worth noting here that there are those that have already made their grievances clear with respect to a lack of choice in who accesses their information. However, there is no solace to be had here. Rather a wake up call. This disgruntled group is not foreign to any one person. However, we might better address this problem if it is reframed as an anger for those that observe us being naked, behind a one way mirror. The feeling of injustice comes from this power dynamic, why should be be so exposed while others are not. The lack of solace comes from the continued observation of the nature of information. The only way forward is that everyone is naked and everyone can see everyone. As the entropy of information becomes ever greater, we will have access to unimaginable capabilities, and yet if we wish to poor our lives into preventing ourselves from being observed, then it will be quite the uphill battle. This is not to say that the implications of information entropy are not serious. There is an ever present risk of impersonation, tailored manipulation, and unrealized authority over our lives. However these hills that might be worth dying on, are a two fold fight. To reject a centralized power structure and its encroaching control over our lives, and to reject a lack of access to individual power and information for all. A fight to reject this power from being had from anyone is a folly pursuit.

[Power Distribution]

Why collapse and tyranny are one in the same.

[Power Distribution: Coordination]

- Why the world this will shift to centralization and tyranny
- Why Centralization is akin to centralization and privacy: block chain

Bitcoin's introduction raised public awareness of blockchain's real-world application as a validated ledger. Ethereum expanded on this by incorporating ownership concepts with Solidity, demonstrating blockchain ledger technology's utility beyond just ownership to include information. However, increased understanding revealed inherent limitations in distributed technologies reliant on asymmetric hash code encryption. Bitcoin's value trends mirrored commodities like gold, functioning as a perceived safeguard during periods of distrust in traditional institutions, lending value to assets independent of state affirmation. Yet, the significant wealth acquired by early adopters led some to view it as a speculative investment, further fueled by brokers facilitating transactions. While some continued to profit, their gains paled in comparison to the initial Bitcoin surge. Beyond early investors, Bitcoin's core utility primarily benefited those seeking to circumvent governmental oversight in financial transactions. These users confidently conducted substantial Bitcoin exchanges due to the difficulty in tracking them, offering an advantage over traditional currencies and commodities. This system relied on widespread faith in Bitcoin's value, even if its intrinsic worth was questionable, with public ignorance contributing to its perceived value. Despite significant theoretical issues, the potential for profit incentivized many to overlook these problems.

The "acknowledgment" of the 51% attack, often mentioned to lend an air of honesty to cryptocurrency discussions, highlights a vulnerability: if 51% of full nodes on a blockchain agree to a false transaction, that falsehood becomes the accepted reality, undermining the blockchain's inherent trust. Initially deemed improbable, the rise of mining pools, driven by the scalability issue, has made this threat more conceivable. These pools, often controlled by entities like the CCP or private investors seeking profit, aggregate the processing power of numerous nodes to increase the likelihood of successfully validating blocks and earning consistent rewards. This centralized power raises concerns.

Furthermore, the inevitable obsolescence of current hash functions, what I term the "hash life" (a play on "half-life"), looms. Despite ongoing efforts by various organizations to develop stronger cryptographic methods, the reality remains that advancements in computing power, whether due to Moore's law regarding semiconductor miniaturization or a broader "Moors

law" encompassing diverse technological progress, will eventually render existing encryption vulnerable. The advent of "software 2.0" and artificial intelligence further underscores this trajectory. Asymmetric encryption, like global warming mitigation, is a temporary solution. Eventually, new methods will be necessary. This inherent limitation means that any distributed technology relying on asymmetric encryption has a limited lifespan of true utility, often sustained by the speculative enthusiasm of a public that may not fully grasp the underlying technical vulnerabilities, leading to a situation that can resemble a decentralized Ponzi scheme.

The fundamental issue is the necessity for fixed programs that require user subscription. When these programs become outdated or require modification, all subscribers face obsolescence. Ethereum partially addressed this by establishing both a cryptocurrency and a related charitable foundation. This gave the foundation authority to educate the public, provide updated software, and disseminate information. They capitalized on the initial enthusiasm for Web 3.0, even as it shifted back towards Web 2.0 (though the term persisted for marketing). Ethereum evolved into a trust-based system to overcome Bitcoin's limitations. However, this resulted in a less distributed ledger with a hierarchy of validators, ultimately falling under US government jurisdiction as a means of managing fiat currency for this quasi-cryptocurrency. This path was seemingly the only way for a cryptocurrency ledger blockchain to endure. The complex reasons behind its divergence from the initial vision are often ignored, and there's little incentive to educate those uninterested in this reality, especially since it would shatter the libertarian ideals once associated with Ethereum.

Have no fear, because the solution is here. Part of the issue with these systems was that they tried to create a system that didn't need updating based on owning information. Owning information is one thing but it is an uphill battle if you would like to own that information but also validate it and also have other people know it's validated but not how and also know that you own a specific thing without letting them know your signature that validates it to them that it's validated. This is more or less asymmetric hash code encryption. Another way to describe it is like a parabola, if you had an f(x) function that =ax^2+bx+c , and you put the y values for different x values one would eventually be able to figure out the *explain simplified key codes*, *Explain asymmetric encryption vs symmetric encryption* So if we take the ownership out of these blockchain systems what we are left with are seemingly infinite IDs that can refer to a finite set of elements that no one person owns but can be rearranged to discover a new form. Much like the Library of Babel algorithm information can be discovered but not createdThe central challenge with previous systems lay in their attempt to create self-updating systems based on information ownership. While owning information might seem straightforward, validating it, proving its validation to others without revealing the validation method, and demonstrating ownership without disclosing the validating signature creates a complex scenario, akin to asymmetric hash code encryption or understanding the underlying function of a parabola (ax^2+bx+c) given only y-values for various x-values.

By removing the concept of ownership from blockchain systems, we are left with a seemingly limitless number of identifiers that can point to a finite collection of items. Although no single entity owns these items, their rearrangement can lead to the discovery of new forms. Similar to the Library of Babel algorithm, information can be found but not generated.

[Power Distribution: Technology and Critical Points]

Discuss the cyclical relationship between technology, power, and societal structures, and the evolution of government.

[Power Distribution: Intentionality]

-
- How might a nation such as the USA uphold its priority to balance the right of an individual and negate an individual from infringing on the rights of another? We must grasp the core issue before attempting solutions.

Other Writings

Why it is important to have the Mycite Framework to support Software	The goal is to have a schema that allows for a class of programs to be written that standardizes a language of information. The schema seeks to describe data semantically. Therefore its main goal is to describe information structurally with a finite number of elements. Doing so by using an algorithmic manner describing what and how content within a space is made up of those elements. Programs without the use of this schema only handle information with respect to themselves and thus the information remains arbitrary subjects of focus. This prevents that information handled by a program from being understood unless it is explicitly designed to. Even if that program is designed to use parts of the information available. The consequence from this becomes more obvious for systems and networks.
Why interoperability is needed for software and how it can be achieved	A robust, static information scheme is necessary to define elementary building blocks for describing future entities. Information must define changing magnitudes while maintaining a static base. Software and hardware should dynamically exist on a standardized information architecture that supports their function without limiting their abilities. Individuals must control the foundational influence of digital tools to truly own their interaction with them. Digital interaction should allow groups to attribute actions to individuals, not environmental influences on tools. We must adapt to inevitable discovery, as hindering adaptation to unstoppable innovation leads to the collapse of rigidly controlled environments. Software and hardware should dynamically exist on a standardized information architecture that supports their function without limiting their abilities. Individuals must control the foundational influence of digital tools to truly own their interaction with them. Digital interaction should allow groups to attribute actions to individuals, not environmental influences on tools.
Automation	Automation, akin to the adoption of simple tools in the age of AI, generally aims to enhance user capabilities. From basic tools like hammers to advanced technology such as automobiles and computers, the common thread is increased user ability. However, complexity in tasks introduces a tension between control and action. For lack of better words, we might call this the difference between automated and smart technology. An alarm clock will follow out the action intended automatically, however, it would be a less than convenient tool if it were to assume when you wanted to wake up. This examines the facet of the controlled directive. Secondly is a system of control's abstraction, in that technologies and machines can be made to abstract the outcome of a user's intention differently for different scenarios. It is still unseen how humans might consider further and further abstractions that are the result of their intended outcome or if at some point they become their own directive. When we apply this to AI's ability to not only train on elements of an arrangeable field, but also its ability to train on decision trees; we see how this sits at a point where the outcomes are not the result of preset decisions, but rather the outcomes that are the results automated decisions, with those decisions be the the result of preset patterns that are encoded for an AI to observe in example data. This displays the continued trend of information manner of increasing in speed and density, as we compound directives of higher and higher intention of output.
Example of a Localized Global Economy:	Barcelona's initiative to become a zero import, zero export city is rooted in its pioneering Fab City strategy, launched from the Institute for Advanced Architecture of Catalonia (IAAC) and the

Barcelona	global Fab Lab network. The city envisions transforming from a linear consumer of global goods into a locally productive, globally connected hub. One where materials are sourced and goods are fabricated locally in digital fabrication labs (Fab Labs), while only digital data (like design files) is imported or exported. By investing in public maker spaces, educational programs, open-source tools, and urban manufacturing policies, Barcelona is creating infrastructure that enables neighborhoods to meet many of their own material needs. This approach demonstrates that any city; with a commitment to open knowledge, community-led innovation, and decentralized production; can feasibly adapt the Fab City model to build local resilience, reduce environmental impact, and democratize production.
Original Introduction; Rather applies for: The Principles of Design	Money is a metric of a person's worth.Yet its value has been distorted by those who have gamed the system and merely rearrange wealth to end up in their pockets. Creating a false image of contribution. Only those that play an additive game of life, creating value on the back of their intention and time, should be rewarded. While some forms of inherent social compensation exist, such as the benefits derived from stable family structures and thriving communities, these are mere reflections of this principled nature. It's crucial to develop social constructs and systems that both promote these beneficial trends and address those that deviate. This is obvious, along with the dually visible pitfalls of any ignoring a design with principles that respect the nature of trade and commerce. Many perceptions linked with wealth are simply reflections of these principles of its nature. Likewise, current societal views on information ownership need reevaluation. To build lasting social agreements, a deep examination of the nature of information is necessary. Failure to adapt will lead any organization or person to an eventual decay and then displacement. Displacement, in place for that which embraces these realities. The current infrastructure and associated economic models are on the cusp of a world that challenges its foundational concepts. What might appear to be disparate problems are, in fact, symptoms of this underlying allegiance to information ownership. Issues of which do not end with current problems but are the root of numerous, even more looming consequences. The public is already well aware of this shift, witnessing the merging of creation and discovery, exemplified by AI language models. Further more is a unanimously understood bystanding to a weakening of democratic principles, manipulations of public assembly reminiscent of 1984, suppression of the press and the decline of journalistic integrity. As a nation made for the people, by the people; we must reflect what has gone awry, such that might allow the proliferation of goods and services that harm our well-being, the robbery of a nation's people to live lives lacking purpose, and communities devoid of connection. Too often, it is said that things have gone too far, but what is not said is that we are willing to bear this pain as opposed to ridding our world of globalization. Every person understands this fact: that if we shed our selves of the shackles that keep us from choosing paths in life that invest in our freedom and independence from technocrats, one that lets a community be connected as well as serve its own economy, health and culture; that we also shed ourselves the ability to prevent those willing to forgo the luxuries of a localized life, from outcompeting and ultimately suffocating out our communities temporary bubble. On the other hand, there is a shared fear among the world's people, of a world without authority and order. How might a future ever be navigated without enforced control given the ever increasing capabilities of artificial intelligence, quantum computing, bio engineering, robotics; limitless creation and destruction. It is easy to let one's mind run into a spiral, considering unstable encryption, the intertwined oligarchy of corporations and government, an inability to tell digital

	reality from digital fiction, an empty academic complex, or even just about one's utter lack of influence over the well being of their immediate environment, occupation, or loved ones. What does banking look like without encryption, how can identity theft be prevented, how might we ever know what's true, will one company own every discovery made by AI. Regardless, there is little room to avoid discourse. Avoidance brought on by an assumption that only two options exist. However, there is a third option, one that economically incentivises localization, without rejecting globalization. One that allows local networks like small farmers to outcompete industrial, globalized-corporate counterparts. We already see cities, such as Barcelona, setting its initiative to become a zero import, zero export city. Rooted in its pioneering Fab City strategy, its aim is to transform from a linear consumer of global goods into a locally productive, globally connected hub. One where materials are sourced and goods are fabricated locally in digital fabrication labs, while only digital design files are imported or exported. This example, at its core, is a socially constructive movement that is built to respect principles that reflect information's true nature. Further consideration of this nature leads one to imagine a future global economy where any assortment of atoms can be reproduced by one person. An economy that only values novelty, time spent, and raw materials. In a world where people support social systems that don't avoid the principles of nature, there is a world of people that are expected to add value with their time, creativity, and thoughtful new ideas. A world where all existing barriers of imagination and creation are eliminated. However, to address current and future challenges, we must first establish a common understanding of these issues to move forward constructively. This report outlines the state of things and proposes a solution, the *Mycite Framework*, a new way of representing and interacting with data. This small change is important for the shifting of how individual-pools of information can be used to support the ocean of information that makes up the internet and digital tools that allow us to have our lives as they exist now. If the world can't be brought to a halt, in order to prevent it from ending, then things must hit the ground running; all while mitigating the effects of future changes and utilizing its benefits. Finally this report details how the tech start up, *FDN*, is implementing the *Mycite Framework* in local agriculture and why it is the most effective and meaningful first step.
Error free nature	Just as the interaction of force, mediated by the boson field, gives existence to particles, so too do struggle and challenges to our desired hierarchies force us to overcome behavioral inertia and adapt—this is life's bottleneck. Interaction equates to change, and change to existence. Information is energy, and its entropy increases as its directional predictability decreases after originating from a source. Like a mailed letter, information can be misplaced, wrongly delivered, altered, or its authenticity questioned despite a signature. While structures can aim for accurate, error-free transmission, eliminating error and fraud entirely remains impossible.
Judgment and sum of Parts	

	Judging an abstract idea's value differs from judging a person's action. An idea's value is like assessing momentum without mass, an arbitrary judgment applicable to anyone. However, judging a person's action denies reality by attempting to evaluate something that simply is. This futile judgment of the past inadvertently judges the present and the immutable. If the past shapes the present, how can one simultaneously lament the past's badness and hope for a good future built upon that bad foundation? Similarly, how can a mind accept a bad present while believing in a good future stemming from that very same, bad present?
Surrealmatics: Intentionality as energy;	People widely accept the power of affirmations and prayer, which share significant parallels. While affirmations alone may not directly lead to achievement, they play a crucial role in psychology by reshaping our thinking. By changing how we perceive ourselves, we can influence our subconscious mind to believe in our capabilities and take control of aspects of our lives we always possessed but didn't recognize. A notable study illustrated this: rats trained to anticipate rescue after 15 minutes of swimming endured for 14 hours, compared to untrained rats who quickly drowned. This highlights the encouraging power of willpower and hope. This concept forms the basis of one aspect of the third law of Surrealmatics: our ability to choose our outlook and control our expectations, thereby altering a reality previously limited by a negative perspective. This limitation stems from a rigid and unchanging logic. Mental health, it's often said, involves accepting reality as it is. This reminds me of feeling frustrated by predictable traffic, acknowledging its inevitability yet still being angered by it – a frustration with reality itself. While acknowledging these emotions without shame is important, recognizing their illogical nature is also key. This example illustrates how our desire for control can extend beyond our grasp. While tenacity in pursuing goals is valuable, a lack of clarity in our priorities can lead to conflicting efforts. For instance, the desire for unhealthy food is instinctual, but a stronger desire for health allows us to consciously reject it. In essence, we desire junk food, but our greater desire for well-being dictates

	our choice. This demonstrates our capacity to create truth and reality, shifting future certainties by intentionality. By remaining intentional, we can avoid the stagnation of past logic and the delusion of future projections. - The Humanity of Focus & View: Something that I have often noticed is said about families with those with down syndrome is that those families depend on have an intuition about emotion and bring light to a room like -
Surrealmatics: Embodiment as Quantum Reality; Choosing madness or death	The past and the future can easily dominate our thoughts, leading to an imbalance. While the future holds boundless potential and innovation, it can also be misleading. It's crucial to ground ourselves in the present moment. For me, the pursuit of invention, with focused attention and perspective, feels like a path to something lasting. Others possess greater or more detailed vision, and they intentionally use these insights as a way to connect with the divine. Just as understanding any language requires effort, comprehending these unique experiences of perceiving more may not come naturally. However, recognizing shared aspects in how we each encounter the sacred allows for a beginning of understanding. Presentness holds a dual nature for me: a state I sometimes wish to accelerate through and, at other times, intentionally linger within. I envision the present moment as an asymptote – existing perpetually on the continuum of time, yet seemingly static. My desire is not to halt progress, but to discover the essence of the present and its equilibrium between future and past, joy and sorrow, known and unknown, allowing for a more infinite existence. This pursuit of truth, despite the acknowledged fallibility of my beliefs, represents my personal quest for eternal life. A furious rage ignites within me at any suggestion that I or others like me are less than human, or that our spiritual pursuits are invalid. While I recognize my imperfections in meditation and prayer, the notion that my prayer is unreal feels like a profound rejection of my very being and intention. This rage once fueled a desire for violent release. However, I increasingly realize that this rage is unproductive. The world is our shared reality, and everyone is on their own imperfect journey toward truth. I lack the capacity to judge the validity of another's spiritual practice, just as I cannot fully comprehend my own. Instead, I can focus on my own connection to the divine and share that with others, hoping to inspire their own unique experiences of the sacred. This rage now often transforms into silent tears of love and awe, a wordless yearning to dedicate my remaining time to nurturing love in the world and striving to reach more hearts. Many highly successful individuals seem unaware of their fundamental powerlessness against the world's forces. They relentlessly strive for control where only influence is possible, losing themselves in a futile endeavor. Conversely, others relinquish control over their own lives despite negative external pressures. While my judgments of these observations may be flawed, the underlying concepts resonate with me. My ambition is to change the world, but I recognize the necessity of collaboration. I aim to avoid the traps that would limit my impact to a single, isolated lifetime, devoid of intergenerational continuity and communal support, ultimately proving to be an exercise in futility. - Communication's Art in God & Godliness in Translation, The lonely god, Art - Reflection and Cyclical Good - Gears and spins, number theory and physics- 3 and * * * - Language Theory

	- Tangled Sex and How We Carry It: The Feminine & the Masculine Spirit of Sex
Anticipating the Future on stable Footing	Time relentlessly progresses, fueling our human tendency to envision the future. However, unfettered imagination can lead to overwhelming possibilities arising from each moment and action. Focusing on the fundamental aspects of our aspirations and projecting their likely progression can provide a more grounded vision of what lies ahead. While the adage suggests studying history to avoid repetition, history in fact evolves, echoing core human elements within new contexts. Growth stemming from this constant human condition exhibits a striking resemblance to the past, not through exact replication, but due to shared underlying components. This necessitates an understanding of "Surrealmatics." This concept serves as both a tool for analysis and an illustration of how current global forces are likely to shape the future, outlining the nature of this progression and its potential destinations.
Surrealmatics: Embodiment as Quantum Reality; The Slope of Consciousness, Finite and Quantum, Logic and Delusion	Matter at its most fundamental level consists of atoms, which are composed of neutrons (neutral), protons (positive), and electrons (negative); a duality echoing the concept of zero, positive, and negative. Electrons possess a quantum property called spin, which can be either positive or negative along the three spatial axes (X, Y, Z), reflecting the three dimensions of space. Delving deeper into the structure of matter reveals a recurring theme of positive and negative attributes, culminating in the Boson Field and its constituent Boson Particle. This particle, with a neutral charge (0), seems to be a foundational element, embodying a spectrum of positive and negative fractional values that rearrange to form the fabric of space and time, as well as the spins and waves that give rise to matter and light. Each fundamental element appears to have an intuitive counterpart, suggesting a principle of balance. However, it's crucial to understand that zero is not the ultimate source from which all existence emanates. Instead, zero itself can be viewed as a positive counterpart to an unfathomable nothingness. Even the term "nothingness" implies a lack, requiring a reference point and thus failing to truly capture its essence. This underlying layer, beneath zero, defies definition beyond the concept of absolute absence or "death." If time were to permeate this realm, it would cease to be this absolute absence, as its "nothing"'s past would then constitute a form of existence. The Boson field's interaction with a stone dropped in water is described not as the stone itself, the splash, or the resulting ripples, but as the very 'action' of the splash, which the field is said to support and embody. This concept can be clarified by imagining a state of prior darkness. In such a realm, the concept of nothingness would not exist until contact is made with 'something.' This interaction would then give rise to the idea of 'nothing' as the absence of that 'something,' as well as the awareness of a right hand implying a left and possibly a left hand. This illustrates that interaction and the exertion of force bring about the existence of particles. Similarly, parallels can be drawn between struggle and challenges to our desires, which compel us to overcome behavioral inertia to adapt. This inherent interaction and subsequent change represent the essence of life. To interact is to change, and to change is to exist. This forms the foundational principle of Surealmatic Mechanics. From the fundamental concepts of Something and Nothing arise the notions of Space and Time, inextricably linked. Considering time's continuous forward progression often leads to visualizations like graphs. A position graph simply plots position against time. The rate of change of position with respect to time is known as slope, and in a position graph, this slope represents velocity. Similarly, acceleration is the rate of change of velocity with respect to time, or the slope of a velocity graph. Higher derivatives, like "Jerk" or "G force," merely extend this concept by adding

	further iterations of "rate of change with respect to time" to the description of position. Understanding this framework is crucial for examining the present moment. The familiar saying, "yesterday is history, tomorrow is a mystery, but today is a gift," highlights that each passing instant solidifies into the immutable past. Conversely, the future holds infinite possibilities. Fixation on either of these extremes can lead to stagnation, effectively halting progress. Overly anxious attempts to control the uncontrollable future, or an immersion in imaginative possibilities, can both divert us from the present. Similarly, a rigid, factual view of reality, perceiving life as a predetermined sequence of events, can also be limiting. James Carse distinguishes between finite games, played to win, and infinite games, played to continue. This resonates with the interplay of reality and possibility, both necessary for meaningful engagement. Intention and expression must converge to create meaningful discourse. One without the other, while holding a degree of truth, lacks full realization. In a physics analogy, our lives resemble vectors with both direction and magnitude. However, at any given point before its conclusion, a life vector's perspective is limited to its immediate experience. Life, as an individual perceives it, becomes their reality at the moment of observation, and ceases to exist for them when they no longer observe it. This perspective could lead to the notion of a temporary personal "godhood," existing infinitely until the point of cessation, beyond which lies the unknown. Yet, individual vector lives constitute the larger fractal pattern of existence. The present moment, though fleeting without conscious focus, offers an asymptotic infinity of potential viewpoints through intentional engagement, potentially leading to profound understanding. This concept of the power of focused presence constitutes the second principle of Surealmatic Mechanics.
Generalist and Specialist	This plays into what can now be foreseen as a future of personal AIs. Maybe managed by a company but ultimately more under the influence and directive of a particular user. This would suggest a world of common folk that now can perform tasks and business that before took entire companies and teams of people to do. Movies, Songs, Financing, and writing, have all become very accessible for people to do by themselves, still allowing them to have the option of focusing on the aspect of a task that they want to perfect. This will ultimately not be an option for some things that require unnegotiable attention to assure precision that we don't want to leave a chance of error. However, even in these instances, an individual or team will likely still use this application to advise their decisions by using the unparalleled ability to navigate large sums of information. The expertise will likely come into play as 'where' to look or maybe rather 'how' to look. These trends point to a greater ability for specialization as well as a greater ability for individual self-sufficiency.
Humans and Artificial Intelligence	Thinking about the Mycelium schema, it is necessary to have a means of organizing information in an architectured order that allows for navigation values to correlate to the location of retrieval. This would exist as a main memory '.wrld' file that exists in a specially related state. Random access memory would then, at the current 'origin' focus level of the current view frame, provide the logarithmic recall of the display field and the surrounding descending display field of focus and subsequently increase the view frame. It feels like artificial intelligence neural networks, at their core, are good at finding patterns of correlation. These values can then be used to amalgamate output variations or search results. One uses correlation values like vectors to correlate fields to preexisting objects (search, position

	probability given values), and the other seems to use correlation values of relational objects like vectors to create probability fields of possible arrangements of values (babelize, create, or correlation values probability given objects). This seems like there is an algorithm that should be able to structurally define inheriter algorithm objects with minimal elements of data and minimal elements of structure, to produce a manner in which any object can exist concerning any other object. This defines the inheriter algorithm upon which this function of search or create can exist in automation. Manually this is done by navigation of existing objects on an inherited order of values and fields that can be pointed in for probability of position or rearrangement of elements within in field of definition. This insinuates that an object (at its simplest, one element of one position capacity) can exist in infinite fields of specificity and at the same time, with every level of increasing position capacity or element value, never exist in infinite, previously falsified derivative directions, fields of infinity. This seems to insinuate that neural network weights exist as a collection of possible relational values given several sets and their application is in the reflection of something concerning this plot; and such, it seems like the human mind's greatest ability is to containerize patterns of objects into objects at varying abstractions, and also reevaluate object necessity of uniformity. A desire to be understood and to communicate arises from this as we desire to test our findings of truth by having them interact with the world, a desire to further examine our observation of truth, and a desire to make harmony.
Technical Discussion	Rudi Group is the set of elemental components that makes all other data and structure up from their re-arrangements. First you get 0, then you get 1, then you get 2, then 3, 4, 5, 6, then 7. With each of these we get a new position to rearrange with and by the essence of other places we get more concepts from which we can gain respective properties from. It is a by product of 6 that we can then gain the rudi of scalar continuity as we gain the ability to encode to our selves by our selves the properties of larger quantities with the addition of three but with the addition of 6 we realize that what comes before and what comes after a point can continue beyond 2 into 3; the defining continuity idea. As for 0 we both 1 and zero as to state that there is anything then in or in itself denotes that there is something. From this we get the ideas of ‘not’ and ‘is’. From this point we now have a space to define what is and is not as we do so we can not move this something anywhere else so in saying that something that is the only thing, in that it is what is not nothing, is ‘not’ we inevitably get 2. We all derive -1 one from this process if we simply look at our one object of focus and combine with it the idea of is, and now we produce what is 1 but not, for 1 is 1 so nothing can be itself in a void such that there is no such thing as it, there is only it. So we see how we arrive upon the two spaces and now have an idea of 2 and an idea of -1. It can also be said that we now have the idea of

something's value by equivalency and by equality but only equal in an opposite polar way. We have not yet gained the x axis as the set of 0, 1 and 2 and the set of -1, 0 and 1 have different being and therefore we can not yet get x without a y, the same way we can not get a positive 1 without first gaining a negative one. Lastly at this instantaneous pit stop we can acknowledge that we have the ideas of not, is equal, is equivalent, is greater, is less than, is congruent, is incongruent, or is something. Now what initiates the third space of existence is our using of the two spaces to set up a statement that ends in is. This is like saying 'C is' for a case which can only result in something like 'A or B' or perhaps and just as possible is' A and B'. From here we can further this into the familiar logic building blocks like so: something or something else, is something and something else, is only something or only something else. We also can derive the idea of something being a scalar number as we can say that something is 1 larger or 2 larger. We also get an idea of what is now, what is before, and what is after. However as I mentioned previously we don't yet have an idea of more forward or more backward yet. However we do have an idea of the x, y and z as we can have these three ideas of something being else in an equal but none equivalent nature. This more or less turns into what one would call the rudi group. These already mostly have names as they are fundamental parts of instruction sets and digital logic system, but what those are missing and what this aims to re-organize is the relational logic that allows these ideas to have ordering information that defines data in a way that is not just the discrete mathematics we derive meaning from by eventually outputting to our selves, but rather creating a spatial awareness of all information to allow us to manipulate it and navigate it with reference to all else. Creating ripple effects and discovering in a way that tries to reflect the primordial forces of the universe that we are so often enamored by in the topic surrounding quantum physics. The goal of this information architecture is to display a synchronicity song, written in the very same thing that it creates.

As the description of something is given it takes up spaces and therefore time, this is the effect of n^n for something's ability to describe information. This is the case as with each space, what came before can be used as a respecting magnitude. This is rarely the case but it is the limit for encoding besides language.

'101'
0000000000000 (x^fibacci) or just x^x
10
(1 or 0)
+ #
then starting with a 1 or a 0 determines whether the following additive number is congruent or opposite in polarity to the initial trajectory (ie. whether to subtract or add), starting with the largest number
in the set that is defined by the largest number less than the intended encoded target.
0: 0: 0
1: 01: 0+1
2: 011: 0+1+1
3: 0
A programm that runs from the command line to take in Hypha Script (HS) input to follow out the denoted commands with the denoted information pointed to or input.
An application I call the Control Gate with an underlying information structure called Tusiary Basic (TB)
Tolkenizes script into Hypha Code (HC) functions from commands or HC data in reference to the HC

	standardized library, for abstraction. Commands written to the terminal also define how information is structured to allow for dimensional interfacing as well as conversion to other file formats. The Cyber Gate acts as a peripheral port manager, internet transceiver manager, and a script and code and compiler swap station/IDE for navigating and manipulating information structures. Part of that interfacing and manipulation is the ability to feed Neural Networks (NN) information given a training model that is also manageable to then also manage the access of that NN deployment and use. Uses the TB Kernel portaler to create interactivity on whatever system it is platformed on and also whatever platform it would like to virtualize. Mycelium Algorithm (MA) creates a schema for spawning babel algorithms that create a schema for spawning any possible arrangement of a set of objects and a bounded field it is given by design from the MA Babel algorithms can be a property file, home file, a parcel file, a room file, a cellar file, or an office file, etc. Also included are bloom files This aims to provide an architecture for a computer to operate on and with fields or information that by their nature exist in a certain form. So property files are used to define device drivers and designations for function executed upon human input device interrupts like the letters denoted by the pressing of a key or the nature of the hypha script command language and how it operates, home files are to act as an updated accounting of how information is stored and compartmentalised, parcel files are meant to define objects made up of poorly organized data, a room file is meant to act as a container for application to allow them to operate with the allotted inputs and storage recall as well as output, a cellar file is a file similar to the home file except that it is designated for a particular content like libraries or applications or application storage or display files (these can be overlapping and used to change the manner of navigation of the home file and its information), the clear file meant to act as a file that contains a tool for writing reading and or editing that operates at a higher level than room files as they are an interfacing gate using the property file level commands to create and control information and its navigation with the exception of changing the property file and the automated process of changing the home file, finally bloom files are meant to act as an interchangeable file that overlay display aspects of a file to allow for optable display customization. The main difference between Tursiary basic and hypha code is that tertiary basic is made up of a few indivisible elements that make up all possible information, while hyphae code is a human readable version of this and thus does not have the ability to be displayed with out the included visual display oscillating libraries that connect a particular object, made up of its position and magnitude, with a particular visual display object. This means to say that somthing that is displayed on a screen has the property of looking as it oes but secondly has the property of representing what it does. This means that apart from a few

	key libraries that exist in the space that can not be read my humans like as they provide the means of allowing humans to read the components that make up the elemental periodic table of hypha code, then hypha
	code has all the re-arangable components to create the foundations of all fields and all data that are combined to create new objects that can be a part of other objects that are then navigated and manipulated
	by the hypha code that defines the structure of the hypha scripting language, from there the hypha scripting language can be used to navigate to levels of abstraction to change the function and controls of applications
	to display data types that are brought about by control gate tools, it can even be used to change the contents of what a control means, and by control I mean the HID signal. This is only possible if you have
	something that is used to make up the thing that can change its self, especially when considering that which does so on a sequential system like a computer with a
	int location; // Bilabial(0), LabialDental(1), Dental(3), Avular(4), Palatal(5), Vular(6), Uvular(7)
	int manner; // Breathed(0), Voiced(1)
	int position; // Concave,(0) Convall(1)
	int vowlition; // Closed(0), Nasal(1), Whistle(2), Elipse(3)
	string writtenEnglish[] = {'A', 'B', 'C', 'D', 'E', 'F', 'G', 'H', 'I', 'J', 'K', 'L', 'M', 'N', 'O', "P", 'Q', 'R', 'S', 'T', 'U', 'V', 'W', 'X', 'Y', 'Z'};
	string writtenEnglishSupports[] = {' ', '.', ',', '?', '!', '"', '\'', ';', ':', '<', '>', '/', '\\', '|', '{', '}', '(', ')', '[', ']', '-', '_', '+', '=', '@', '#', '$', '%', '^', '&', '*', '`', '~'}
	string basetenNumberSystem[] = {'0', '1', '2', '3', '4', '5', '6', '7', '8', '9'}

Topics to Consider	- Effects of Reform - Alternative models - Neural Networks, Quantum Computing, and Sensory Interfacing - Communication: Language and Code, Transmission, Encryption, Entropy - Innovation: Technology and Government, Discovery and Creation, The Human Fractal, and Asymptotic realities - Power: Automation & Control, Optibility, Hyperspecialization & Generalization, Institutions and Commodities - Concerns of: Gene editing, Freedom to self sustain, Freedom to participate and confer with AI, the rights of people to control how their actions are taken as directives by tools, the ability for AI to enable people without enslaving the public to centralised authorities, ect.
Encoding Visualization of Structure	This visualization represents structure through encoding, utilizing a unit sphere with infinite points. This sphere symbolizes the concept of oneness – a singular entity encompassing everything. To understand this visual, consider the XYZ values of a vector within this realm where values are never less than one. Similar to a qubit, each defined value of one or zero for the x, y, or z axis dictates either a flip in the direction of that specification or a continuation in the division of that space. To illustrate, setting X to 101, Y to 001, and Z to 110 involves manipulating a vector's endpoint on a sphere's surface. Initially, the point is shifted by half the circumference positively in the X and Z directions and negatively in the Y direction. Considering the eight possible sections for

	XYZ as (000, 100, 010, 110, 001, 101, 011, 111), our example continues: the first step moves us to the 6th first magnitude surface point, a jump of one-quarter the sphere's circumference positively along Z and negatively along X and Y. Finally, an eighth of the circumference is traversed positively along X and Y, and negatively along Z. This visualization provides a physical space representing fractional surface points, enabling the organization of infinite spaces defined by three unit directions. At each specific point, a fundamental fractal parallelepiped with unit length, height, and depth is established. However, as the location of a point is defined with greater specificity, the potential detail within this factorial parallelepiped—acting as a plane for rearrangeable units and the specification of these units—expands. This unit growth follows a qubit exponential model. Nevertheless, highly intricate fields are often unnecessary in the presence of abstraction, as a defined point can serve as a building block for objects, which can then function as reusable components in other fields. This framework enables the description of objects based on their fundamental properties, providing a basis for a universal interconnectedness of concepts, rather than relying on arbitrary definitions. It also facilitates a unified interpretation of all object information and data, with a foundational capability to derive alternative meanings. Regarding identification, an individual's unique origin in time and space can serve as the basis for an ID fractal, which can be continuously refined for greater specificity.
